Design Triangulation as a Path for Biological Inquiry

Proposal for a Method of
Design-Enabled Biological Research

12 September 2020

Professor Scott Minnich
Microbiology
University of Idaho
USA

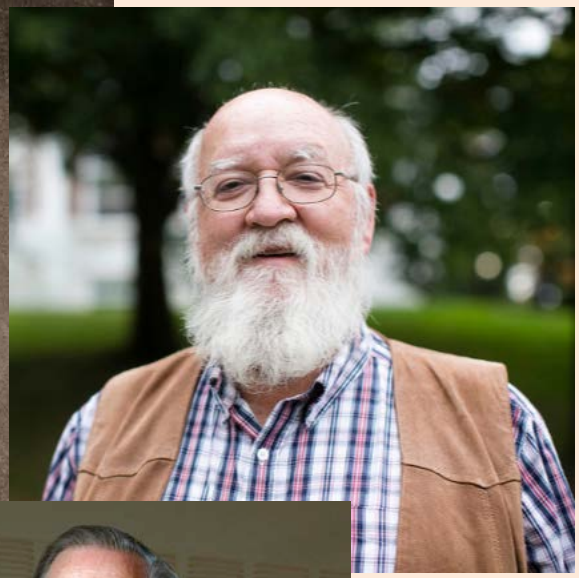
When I first met Scott Minnich in the mid-1990s, when I was still a graduate student, he told he something I have never forgotten:

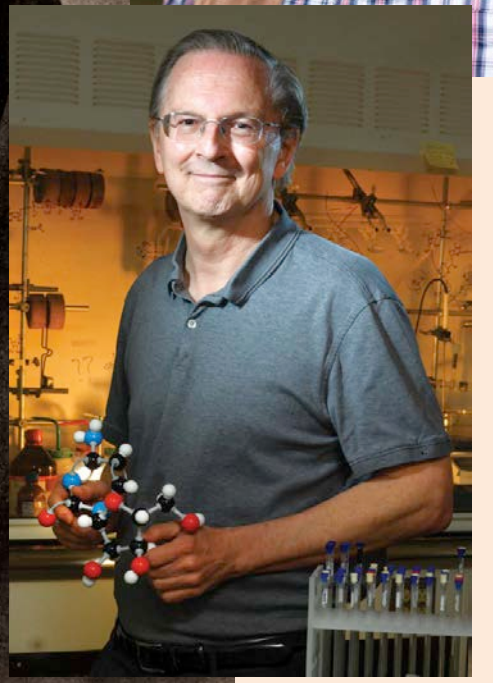
"Paul, none of this intelligent design debate should be all that controversial. **The reality, whether anyone is conscious of it or not, is this: most molecular biologists are *de facto* design theorists already."**

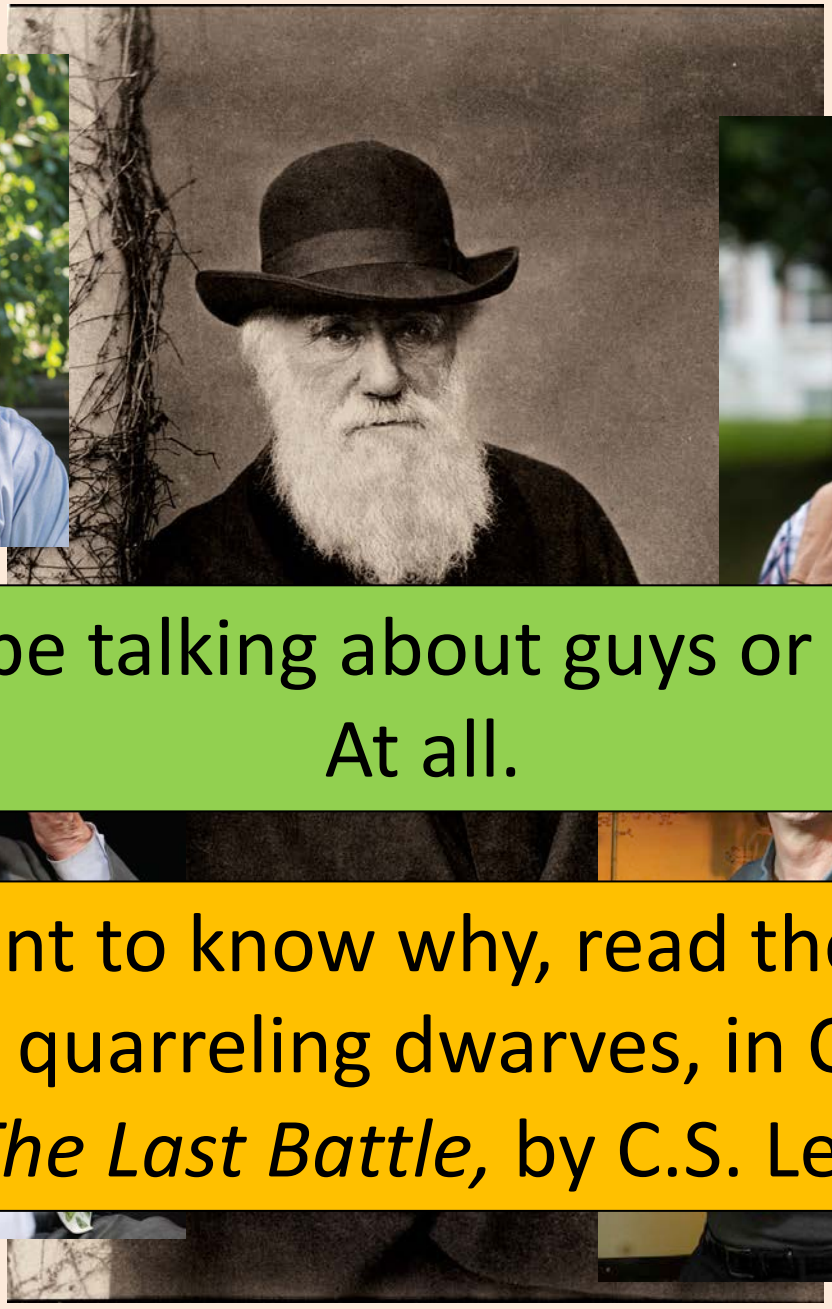
And, he added, they have been doing that for a very long time indeed.

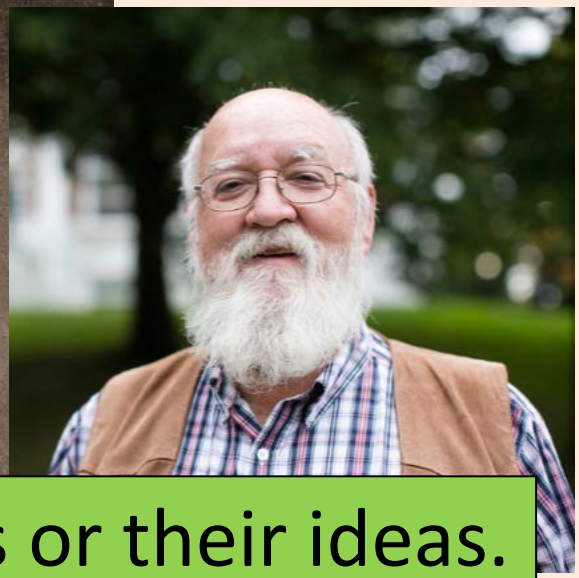
But how could that be possible – even as a *de facto* practice – when design was widely seen as intrinsically unscientific, employing a cause (i.e., a transcendent mind) understood to be unobservable in principle?

In this talk, I explain what Scott meant, and why it matters, using an idea called "design triangulation."









We won't be talking about guys or their ideas. At all.

If you want to know why, read the episode about the quarreling dwarves, in Chapter 13 of *The Last Battle,* by C.S. Lewis.

And that's pretty much
all you are going to hear
about evolution in this
presentation.

There's a bit more (for
explanatory purposes only)
in the big pdf coming next week.

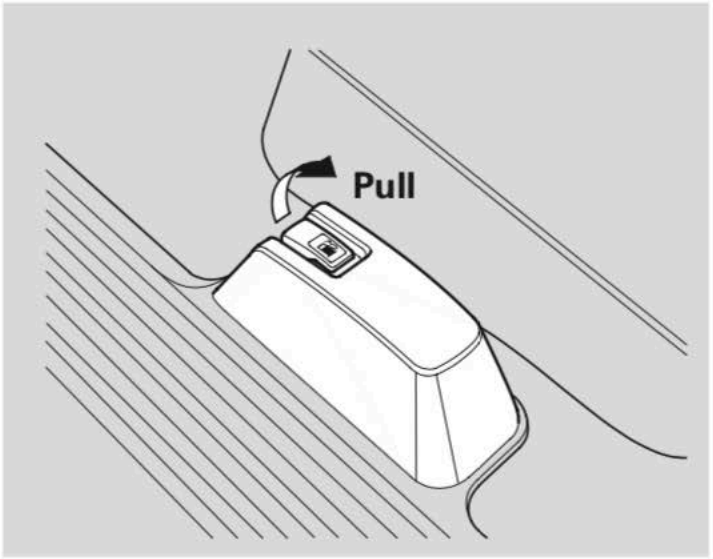
I.

Why won't the sliding door of my Honda Odyssey open?

The basic logic of functional triangulation

Let's start with my 2003 Honda Odyssey.

Filling the Fuel Tank



1. Because the fuel fill cap is on the driver's side of the vehicle, park with that side closest to the service station pumps.

2. Open the fuel fill door by pulling on the handle to the left of the driver's seat.

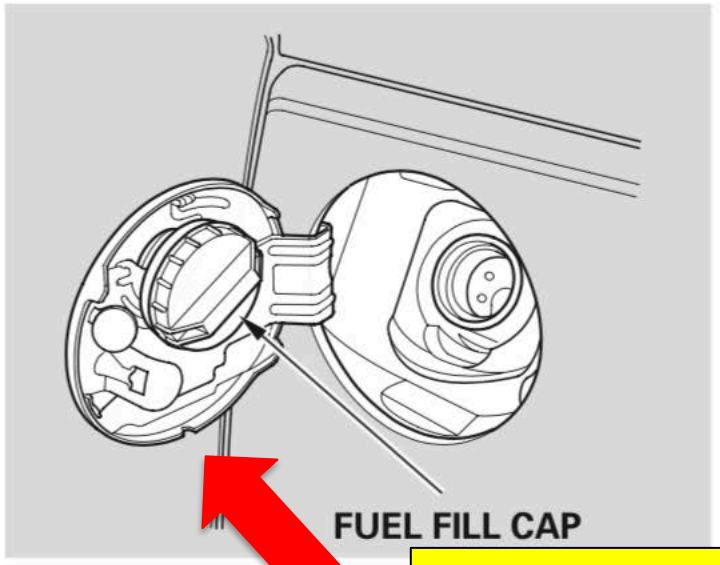
Before refueling, make sure the rear sliding door on the driver's side is closed.

BUT WHY?

⚠ WARNING

Gasoline is highly flammable and explosive. You can be burned or seriously injured when handling fuel.

- Stop the engine and keep heat, sparks, and flame away.
- Handle fuel only outdoors.
- Wipe up spills immediately.



(here's a clue)

Why do I need to make sure, Honda Corporation?

Because two macroscopic objects with mass (like doors) cannot occupy the same location in space at the same time.

And if you're stupid enough to try (Paul), *we've designed the car to deal with that.*

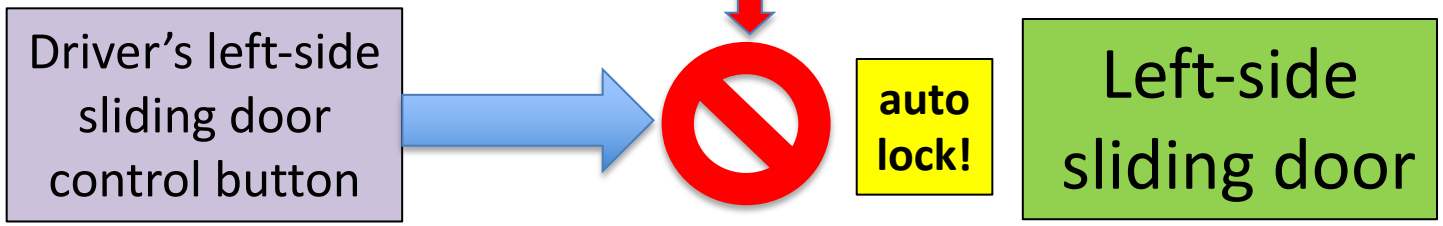
A Note About Refueling

Before refueling, make sure the driver's side sliding door is fully closed. When you release the fuel fill door, the driver's side sliding door automatically locks so it cannot open and interfere with the fuel door.

During the design ("foresight") stage of Odyssey development:

Honda engineers: hey, some drivers are clueless. They'll need help so they won't jam the driver's side sliding door.

Wait a minute, ***is the fuel door open?***



Now suppose you are Paul's younger brother Peter Nelson MD – who is a situationally aware and clued-in person, not a badly distracted philosopher of science.

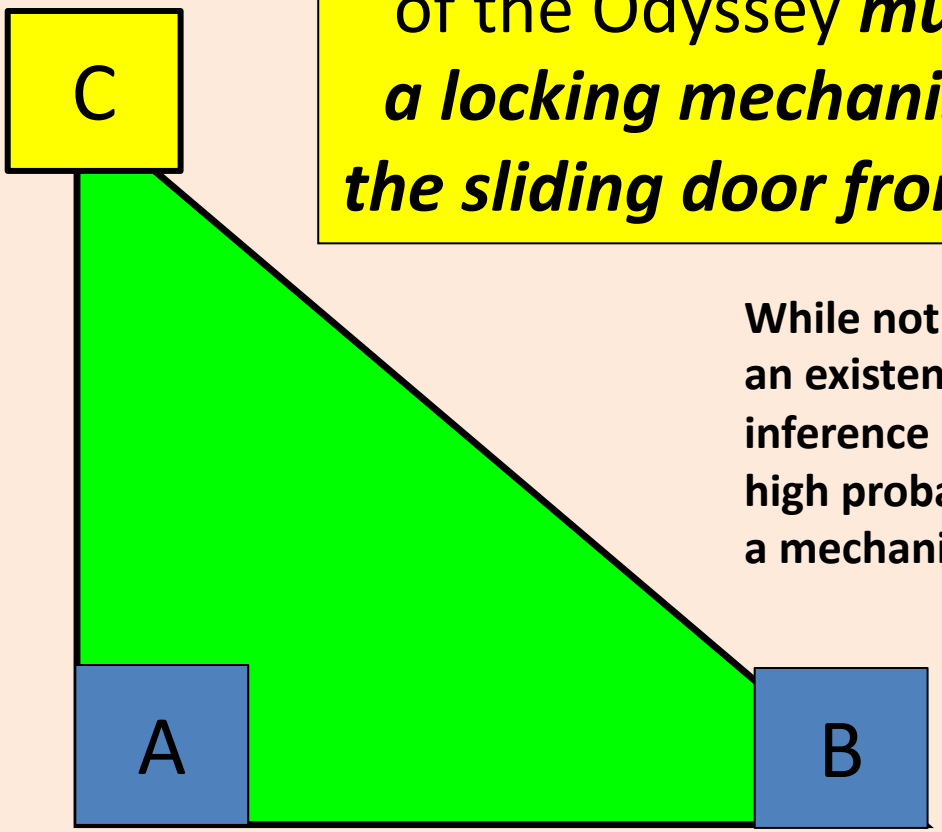
Peter, who is not an Odyssey owner, and has no experience with this vehicle, studies the minivan doors (sliding and fuel) while waiting for me in the driveway. He says to himself – hmm:

Honda must have a foolsafe mechanism to prevent door jamming.

Peter triangulates to an unobserved, but necessary, function of the system, as follows.

Functional triangulation (everyday version):

Therefore, the global design of the Odyssey ***must include a locking mechanism to stop the sliding door from jamming***.

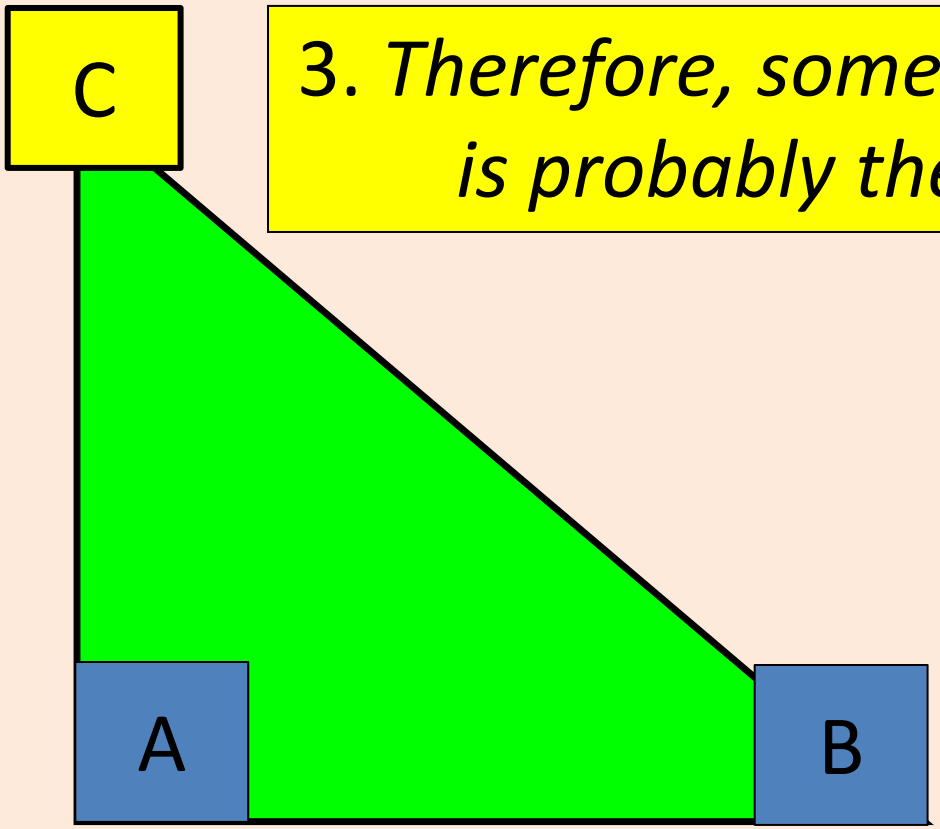


While not strictly speaking an existence proof, this inference confers a very high probability that such a mechanism operates.

The sliding door moves to left rear, over the fuel door.

If the fuel door is open, the sliding door would jam.

Triangulation as a metaphor for scientific inquiry:

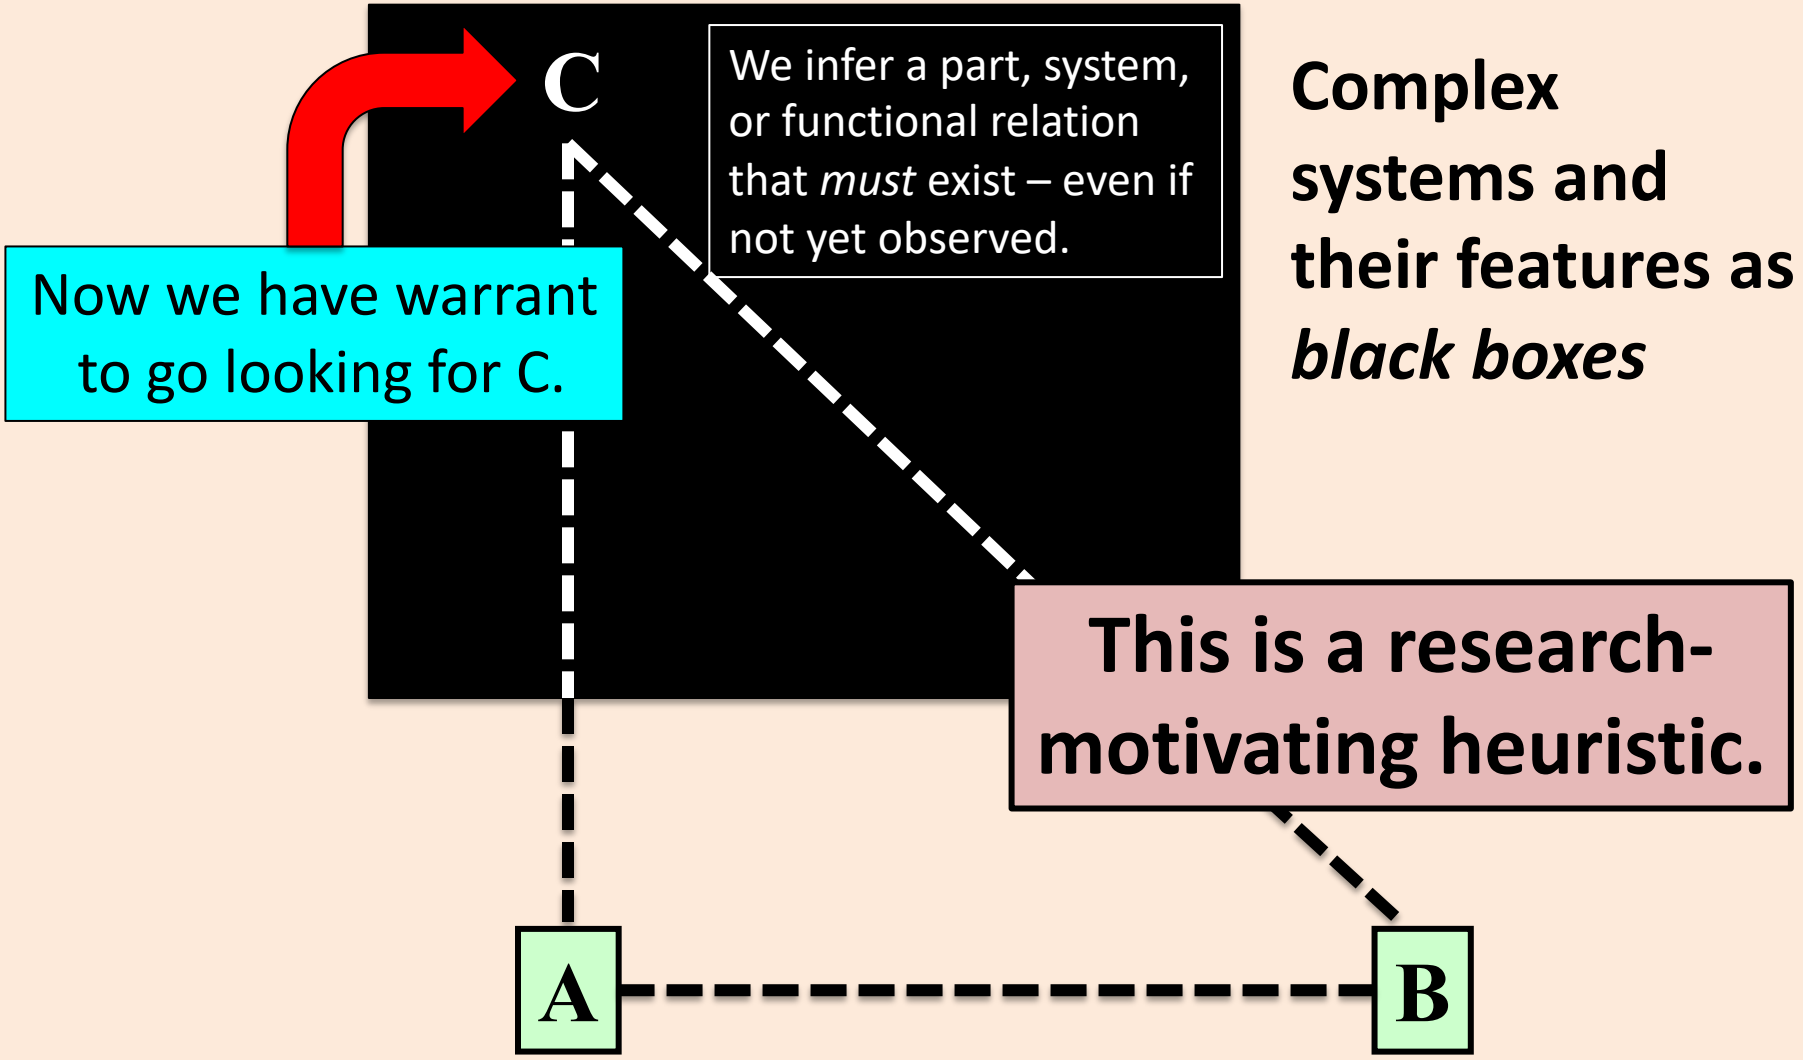


3. *Therefore, something like C is probably the case.*

1. We know A.

2. We know B.

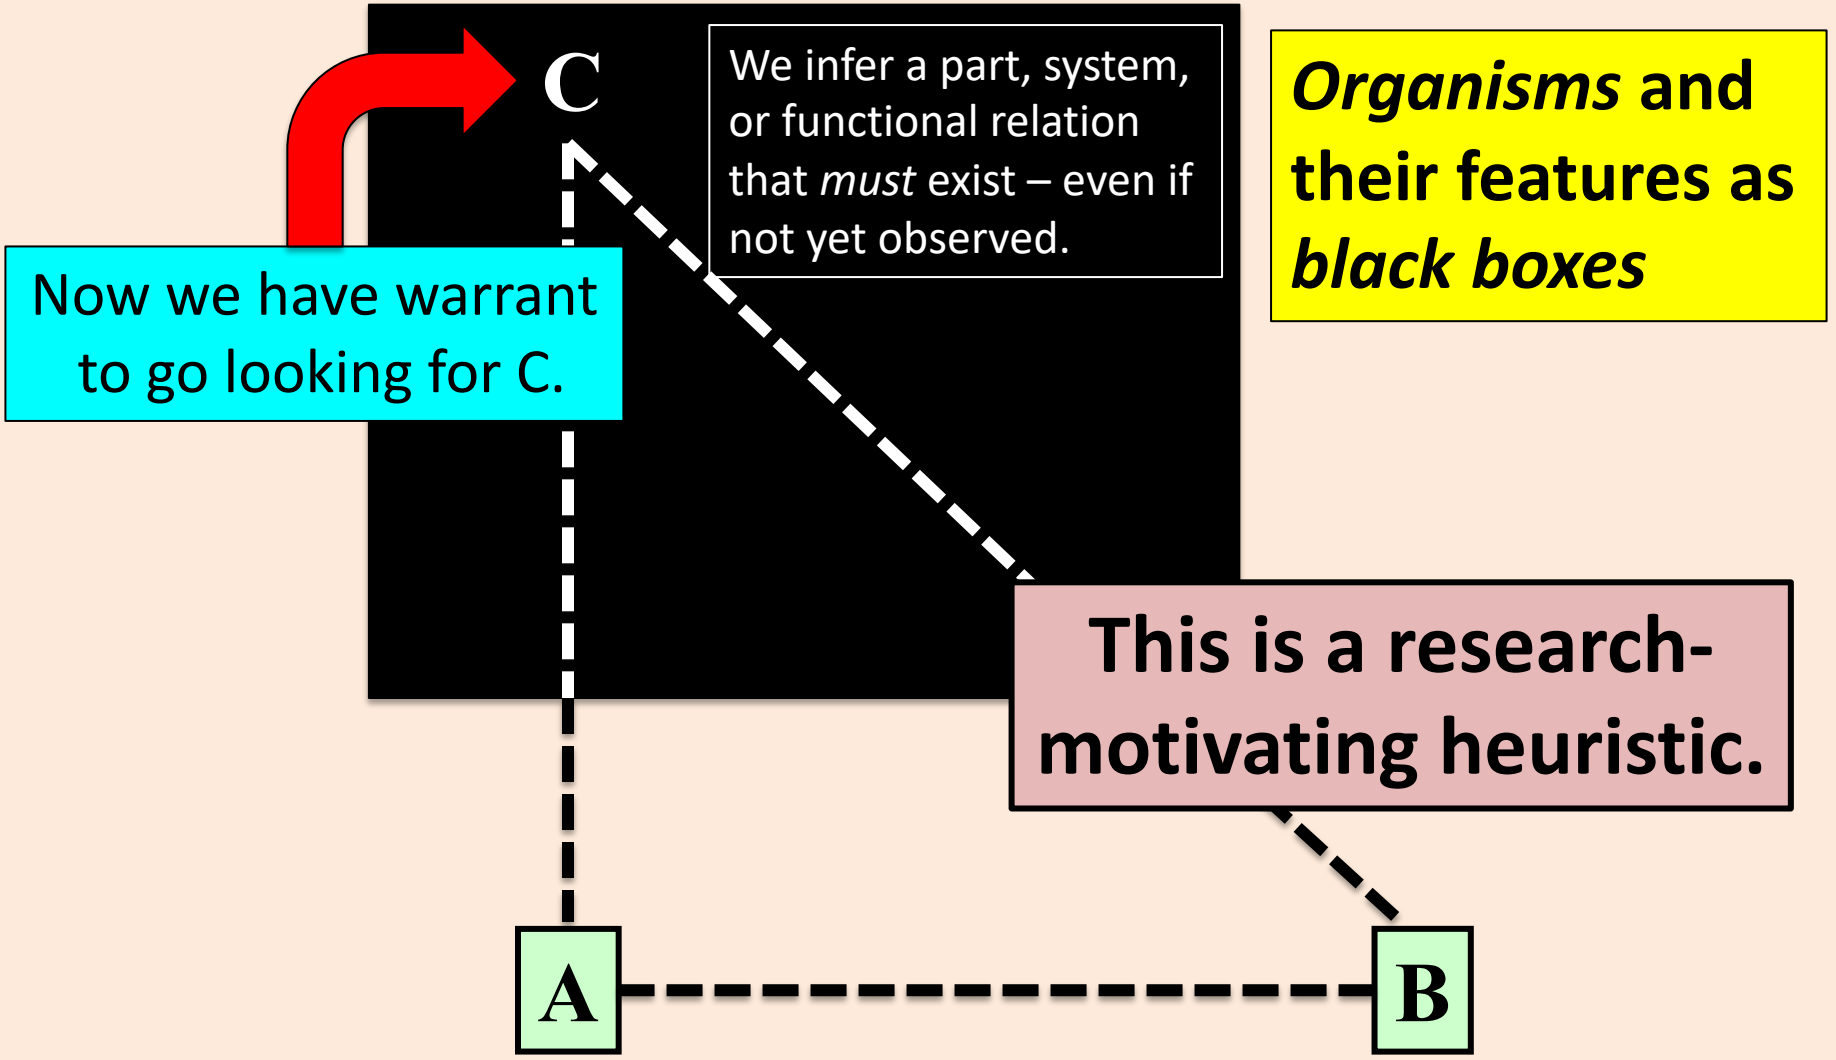
Functional triangulation



Complex systems and their features as *black boxes*

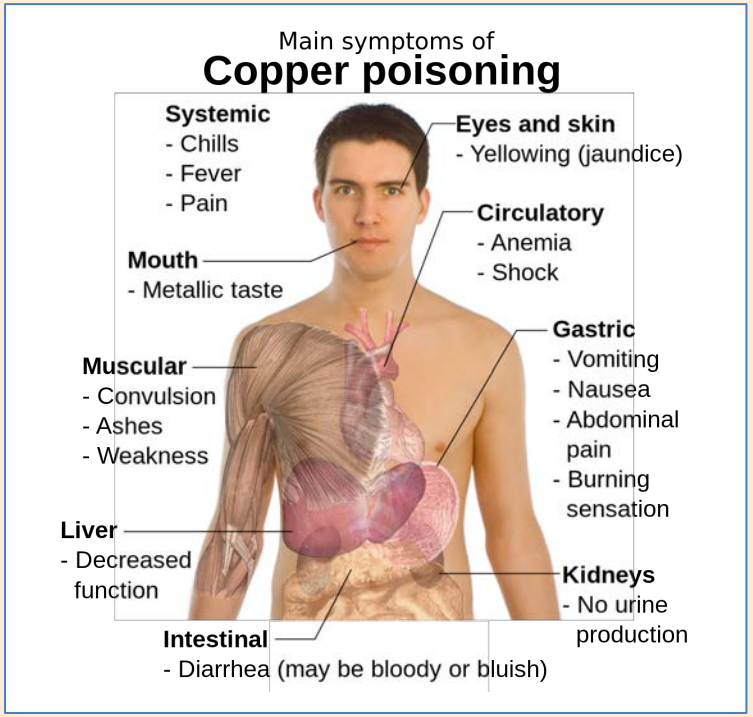
II.
Functional triangulation in biology

Let's try a thought experiment.



Consider a pair of biologically related facts:

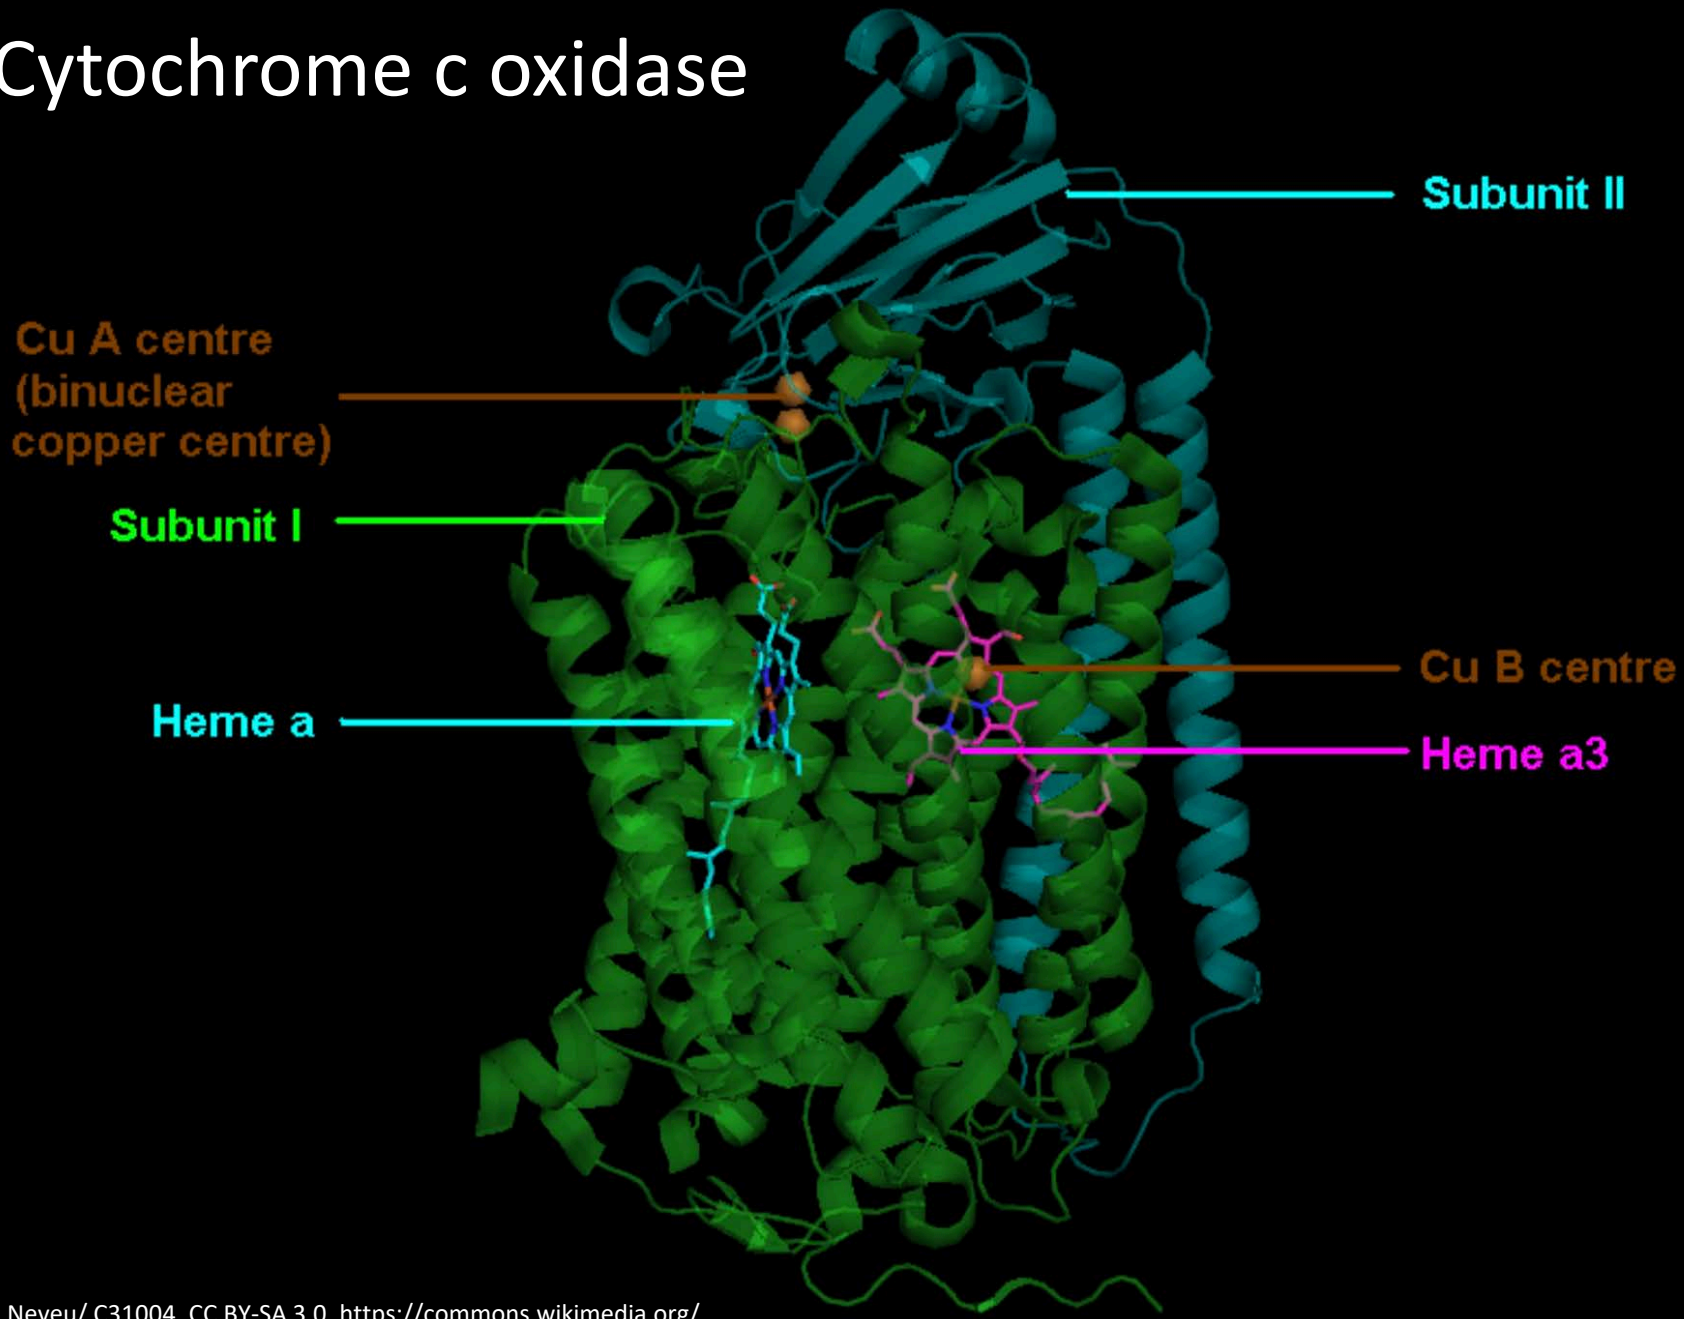
1. **Copper is a poison.**



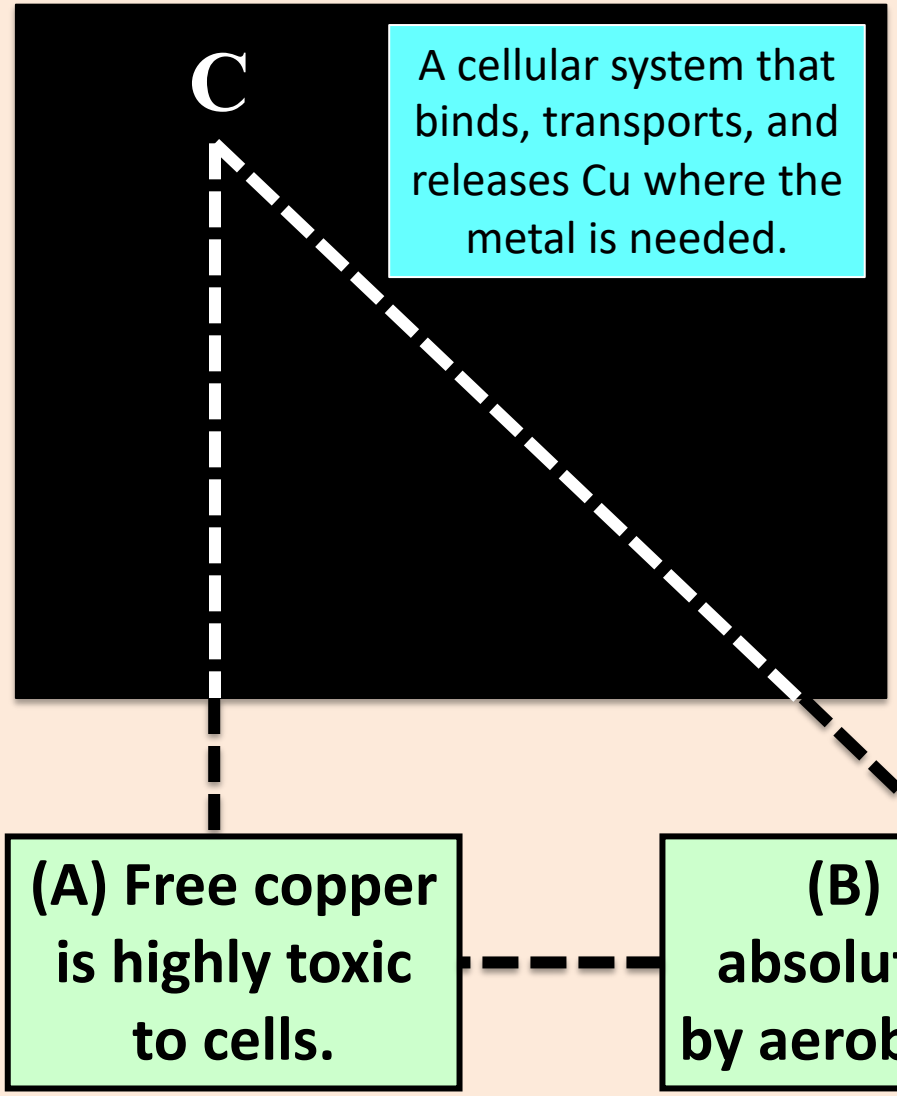
2. **Copper is absolutely required by aerobically respiring organisms (like you), as an essential co-factor in several enzymes.**

(illustration credit Mikael Häggström, Wikicommons)

Cytochrome c oxidase



Trust the logic: triangulate.



What MUST exist in aerobically respiring organisms?

“But wait a second, Paul…how can you be *certain* the copper-binding system is really there in the cell?”

Don’t worry: it’s there.

Organisms make use of mechanisms for their very viability; whether we see the mechanisms or not, *they exist*.

Call this the ***no magic principle***.

This "existence proof" for a Cu binding & transport system was acknowledged *long before* the system was actually observed:

"Copper is absolutely required for aerobic life, and yet, paradoxically, is highly toxic. … This apparent contradiction has been rationalized by assuming that Cu, like other redox-active metals, is sequestered in nonactive forms as it is transported through cellular compartments."

Valentine and Gralla, *Science* 278 (1997):817.

This "existence proof" for a Cu binding & transport system was acknowledged *long before* the system was actually observed:

"However, the agents of such trafficking and the mechanisms of delivery of Cu to its final destinations have, until recently, remained largely unknown."

Valentine and Gralla, *Science* 278 (1997):817.

Metal Ion Chaperone Function of the Soluble Cu(I) Receptor Atx1

R. A. Pufahl, C. P. Singer, K. L. Peariso, S.-J. Lin, P. J. Schmidt, C. J. Fahrni, V. Cizewski Culotta, J. E. Penner-Hahn, T. V. O'Halloran*

Reactive and potentially toxic cofactors such as copper ions are imported into eukaryotic cells and incorporated into target proteins by unknown mechanisms. Atx1, a prototypical copper chaperone protein from yeast, has now been shown to act as a soluble cytoplasmic copper(I) receptor that can adopt either a two- or three-coordinate metal center in the active site. Atx1 also associated directly with the Atx1-like cytosolic domains of Ccc2, a vesicular protein defined in genetic studies as a member of the copper-trafficking pathway. The unusual structure and dynamics of Atx1 suggest a copper exchange function for this protein and related domains in the Menkes and Wilson disease proteins.

Although Cu is an essential cofactor for mitochondrial, cytosolic, and vesicular oxygen-processing enzymes (*1*), it can be toxic even at low concentrations. Cu(I) and Cu(II) ions can bind with high affinity to adventitious sites in partially folded proteins and catalyze auto-oxidation of lipids, proteins, and nucleic acids. To investigate the mechanisms by which cells overcome the dilemma of maintaining Cu availability while controlling deleterious reactivity of the free ions, we have determined the Cu chemistry and Cu-handling function of Atx1, an intracellular eukaryotic protein implicated in Cu trafficking. Our results indicate that Atx1 functions as a metal ion chaperone, a protein that protects and guides Cu(I) ions to activate target enzymes.

ATX1 is one of several genes in the Cu-dependent, high-affinity iron uptake pathway in yeast. These genes encode Ctr1, a Cu uptake protein in the plasma membrane; Ccc2, an intracellular membrane protein; and the multicopper oxidase Fet3 (*2*–*6*). Although the role of Fet3 in iron uptake is unclear, Cu loading into this enzyme occurs in a post-Golgi vesicle and is mediated by Ccc2 (*4*). The *ATX1* gene and its human homolog, *HAH1*, encode cytosolic proteins implicated in Cu trafficking to these Ccc2-containing vesicles (*7*–*9*). The Ccc2 protein in yeast and its human homologs, the Menkes disease protein (*10*) and Wilson disease protein (*11*), are members of the P-type adenosine triphosphatase (ATPase) cation transporter family (*12*) and are present in the membranes of secretory vesicles (*13*). Each transporter contains two or more Atx1-like cytoplasmic domains (Fig. 1), the functions of which are not known. The conserved MTCXXC sequence (X, any residue), a motif observed in several bacterial Hg(II) transport proteins (*14*), is thought to be a Cu binding site, although it does not correspond to known Cu(I) or Cu(II) sites in structurally characterized proteins. Establishing the Cu oxidation state and coordination environment in Atx1 should provide insight into its function and that of the homologous domains in its partner proteins.

Atx1 was expressed in *Escherichia coli* and purified as the apoprotein (*15*). Addition of $CuSO_4$ to apo-Atx1 in the presence of excess thiol reproducibly yielded a complex with a copper/protein ratio of 0.6 to 0.8 (*16*). Gel filtration experiments indicated that the predominant form of the protein was a monomer under these conditions, regardless of the presence or absence of Cu (*15*). The Cu oxidation state was investigated by electron paramagnetic resonance (EPR) spectroscopy and x-ray absorption spectroscopy (XAS). No EPR signal was observed at 77 K, suggesting the absence of a mononuclear Cu(II) site. XAS experiments (*17*) indicated that the bulk sample contained Cu(I). The Cu-Atx1 x-ray absorption near edge structure (XANES) spectrum exhibited a weak shoulder at 8984 eV, which is typical of Cu(I) and inconsistent with comparable edge features for Cu(II) compounds, the energies of which are 3 to 4 eV greater (Fig. 2A). The intensity of the 8984-eV transition varies with Cu(I) geometry, ranging from low for tetrahedral sites to high and well resolved for digonal sites (*18*). The observed transition is typical of those of trigonal Cu(I) model compounds (Fig. 2A). Mononuclear Cu(I) coordination complexes, however, are usually not stable in aqueous solution, and typically undergo auto-oxidation or disproportionation reactions to give Cu(II) (aqueous) and Cu(solid). In contrast, millimolar concentrations of Cu(I)-Atx1 are stable in air at neutral pH for at least 30 min (*16*), suggesting that the coordination environment in Atx1 stabilizes the Cu(I) state and suppresses disproportionation.

Proteins that stabilize Cu(I) form either polynuclear metal thiolate clusters, as in metallothionein and the transcription factors Ace1, CUP2, and AMT (*19*), or a constrained His_3Cys coordination environment, as in blue copper proteins (*20*). In contrast, extended x-ray absorption fine structure (EXAFS) measurements indicated that Atx1 stabilization of Cu(I) is achieved in a mononuclear site through an all-sulfur coordination environment (Fig. 2B). The high intensity and relatively high frequency of the EXAFS oscillations were typical of those observed for Cu-S interactions. The data could be modeled with a single three-sulfur (3S) shell with a Cu-S distance of 2.26 Å; however, the Debye-Waller factor, σ^2, was somewhat larger than expected (7×10^{-3} Å^2). This Cu-S distance is typical of three-coordinate Cu (*21*–*23*) and is 0.1 Å longer than that in two-coordinate Cu-thiolate complexes (*24*). Given that Atx1 contains only two conserved cysteine residues, the third ligand can be either a low-Z (atomic number) ligand (O or N), a methionine sulfur, or an exogenous thiol. A 2S + 1S fit with a shell of two sulfurs at 2.25 Å and a shell of one sulfur at 2.40 Å reproduced the data better than did the single-shell fit, and gave more reasonable σ^2 values (3×10^{-3} and 5×10^{-3} to 6×10^{-3} Å^2, respectively). Furthermore, attempts to model the data with a shell of 2S and a low-Z shell (1N) gave chemically unrealistic Debye-Waller factors for the N shell ($\sigma^2 \approx 0$).

The 2S + 1S result is unexpected for several reasons. The most common coordination environment for Cu(I) complexes is distorted four-coordinate, and there are few precedents among mononuclear Cu(I) complexes for the low-coordination number environ-

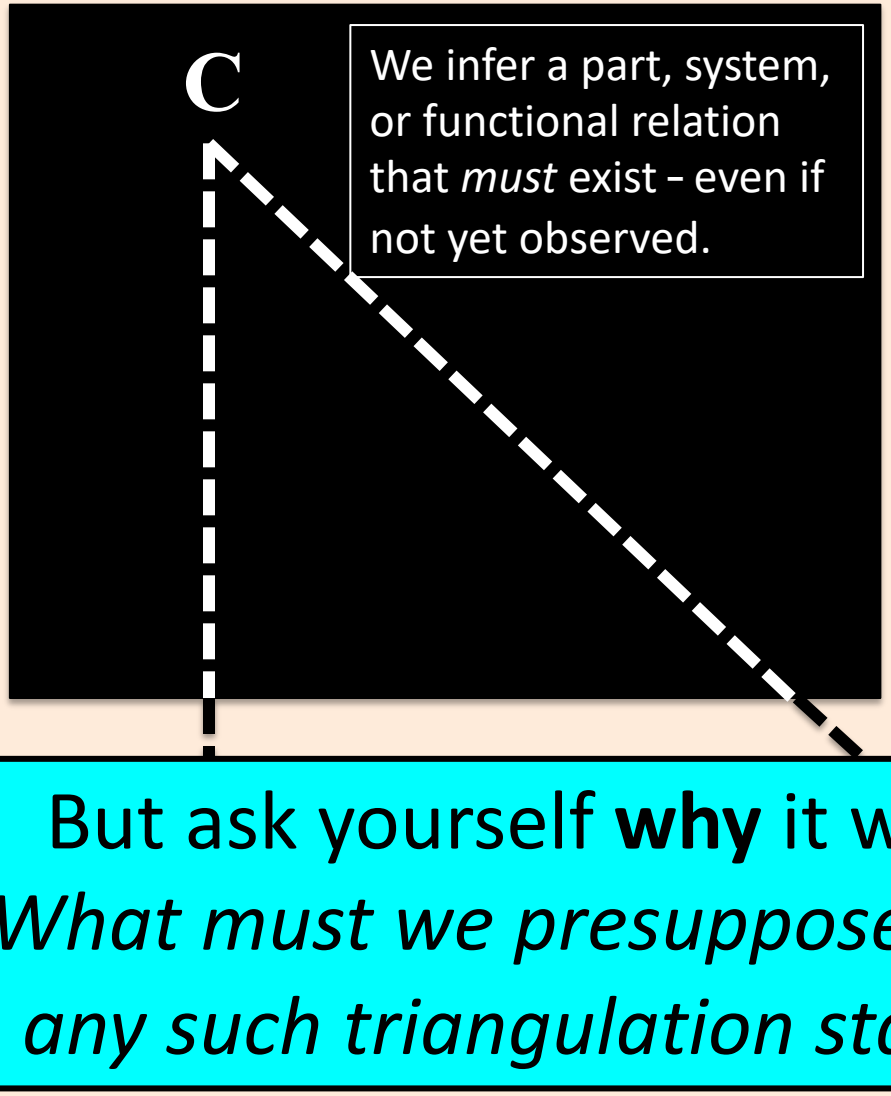
R.A. Pufahl *et al*., "Metal Ion Chaperone Function of the Soluble Cu(I) Receptor Atx1," *Science* 278 (1997):853-856

By delivering essential cofactors or substrates to apoenzymes, the emerging class of metal ion chaperones facilitates formation of an active state of a protein. These chaperones guide metal ions to their appropriate biological partners and protect them from being trapped at adventitious sites. They may also protect cellular components by sequestering specific ions or inorganic clusters (34) and preventing adverse reactions. Our results underscore the idea that cells make use of elaborate machinery for recruiting, trafficking, compartmentalizing, and, ultimately, inserting into the appropriate enzyme reactive cofactors such as mononuclear Cu ions. The intracellular activation of apometalloenzymes by binding of the correct metal ion cofactors is unlikely to proceed by spontaneous self-assembly. Rather, metal insertion is emerging as an orchestrated event controlled by metal ion transport and chaperone proteins whose functions are kinetically and thermodynamically coupled.

This works. **The big pdf has more examples, from the history of biology and today.**



Organisms and their features as *black boxes*

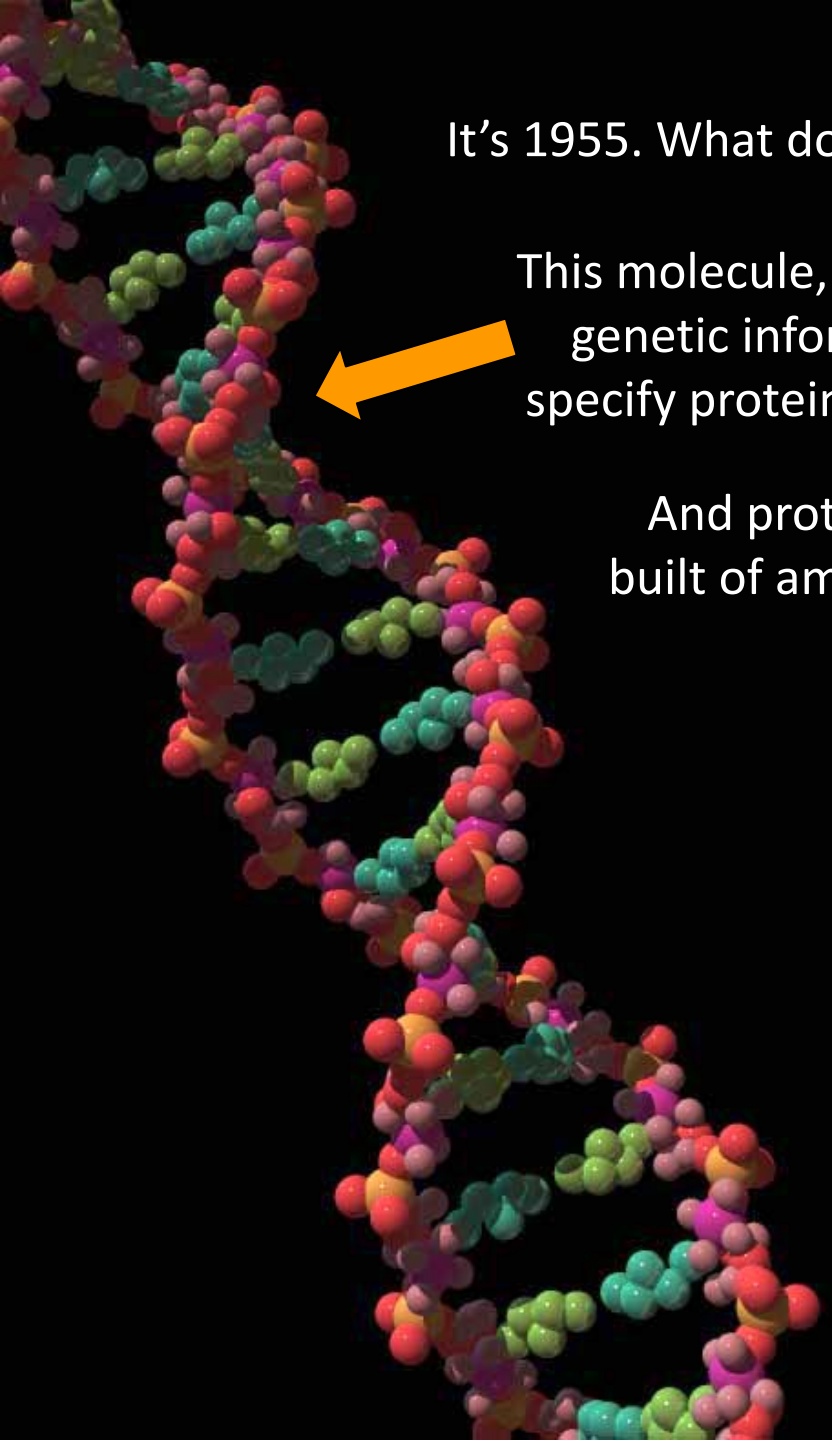
But ask yourself **why** it works.
What must we presuppose to get any such triangulation started?

The next example
is the most telling – and
also carries the answer to
the question “Why does
functional triangulation ***work***
in biology...and why should
we call it ***design*** triangulation?”

III.
The luckiest guess in the history of science – ever.

What I'm going to describe next wasn't a ***guess*** at all, of course.

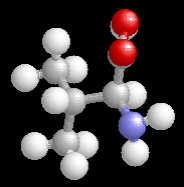
It was a rational inference, using functional triangulation.



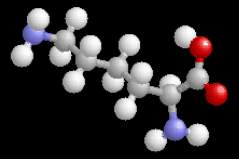
It's 1955. What do biologists know?

This molecule, DNA, carries genetic information to specify protein sequences.

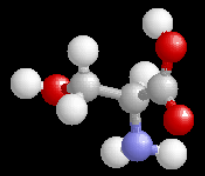
And proteins are built of amino acids.



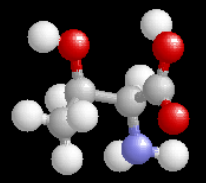
Valine



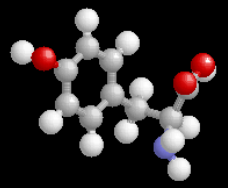
Lysine



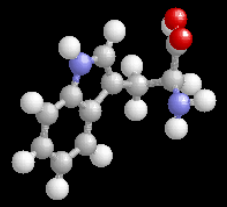
Serine



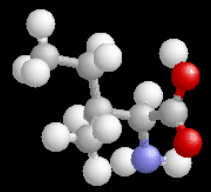
Threonine



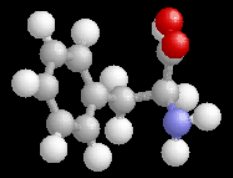
Tyrosine



Tryptophan



Isoleucine



Phenylalanine

But what is mediating information transfer between these two very different chemistries?

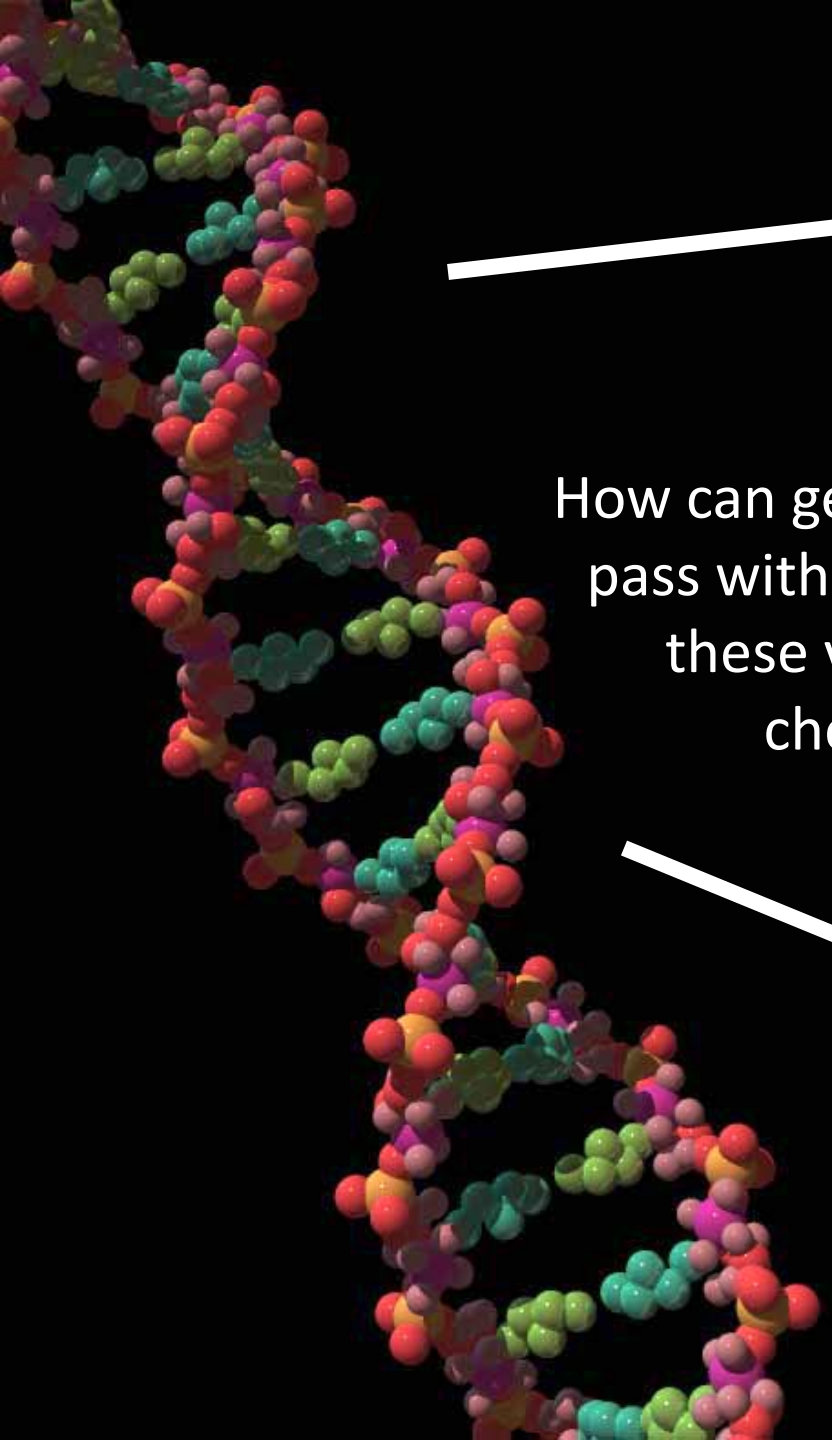
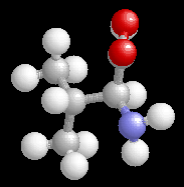
the Molecular Structure of Biological Systems,

Cavendish Laboratory, Cambridge, England.

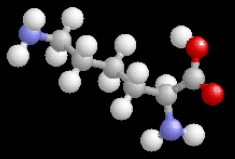
(Crick's original manuscript is available for downloading as a pdf here:
https://profiles.nlm.nih.gov/spotlight/sc/catalog/nlm:nlmuid-101584582X73-doc)



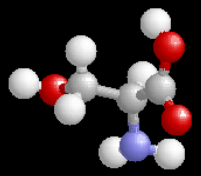
How can genetic information pass with fidelity between these very different chemistries?



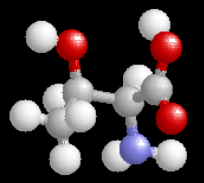
Valine



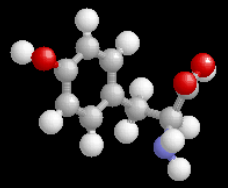
Lysine



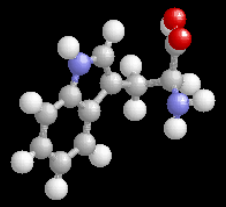
Serine



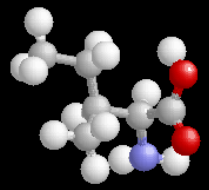
Threonine



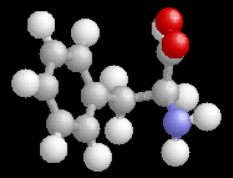
Tryptophan



Tyrosine



Phenylalanine



Isoleucine

Crick (1955) grasps the difficulty:

"Now what I find profoundly disturbing is that I cannot conceive of *any* structure (for either nucleic acid) acting as a direct template for amino acids, or at least as a specific template....I don't think anybody looking at DNA or RNA would think of them as templates for amino acids."

Crick (1955) grasps the difficulty:

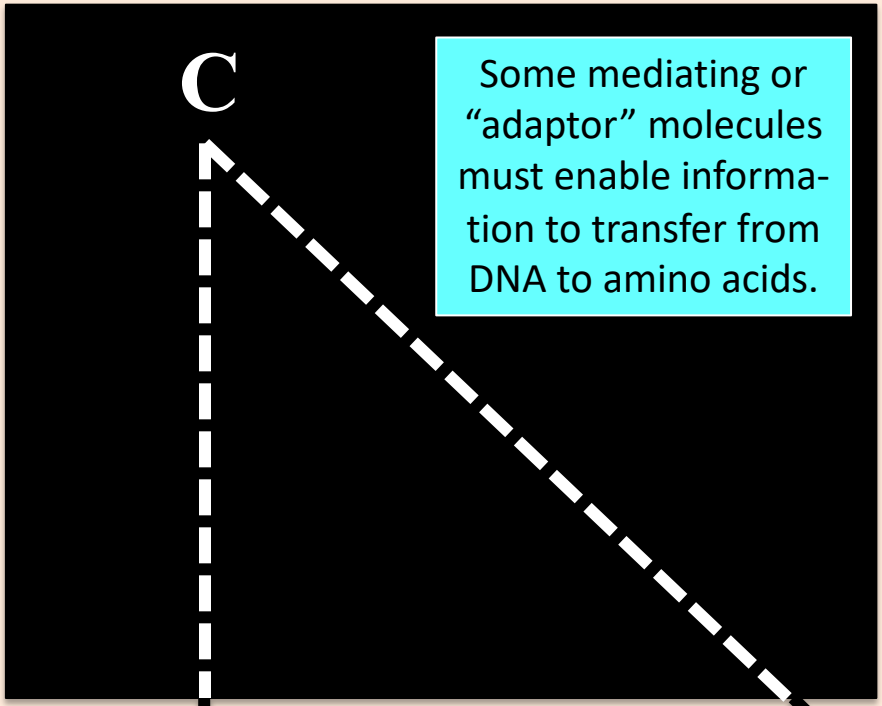
"Where are the knobly hydrophobic surfaces to distinguish valine from leucine and isoleucine? Where are the charged groups, in specific positions, to go with the acidic and basic amino acids?...What the DNA structure *does* show (and probably RNA will do the same) is a specific pattern of *hydrogen bonds*, and very little else."

Functional triangulation, however, underwrites inferences to unobserved entities which ***must*** exist:

When one discovers a complex system performing specialized functions, *assume that a rational logic, and well-matched parts, are enabling the functions.*

No magic. Look for the mechanism: it's there.

Crick triangulates from the cell's information-transfer requirements to its unobserved, but functionally necessary, parts:



Okay, now we can go looking for the system. Here are some of the features it will need to specify each of 20 amino acids in protein assembly...

(A) DNA carries information, but is chemically non-specific ("hydrogen bonds, little else")

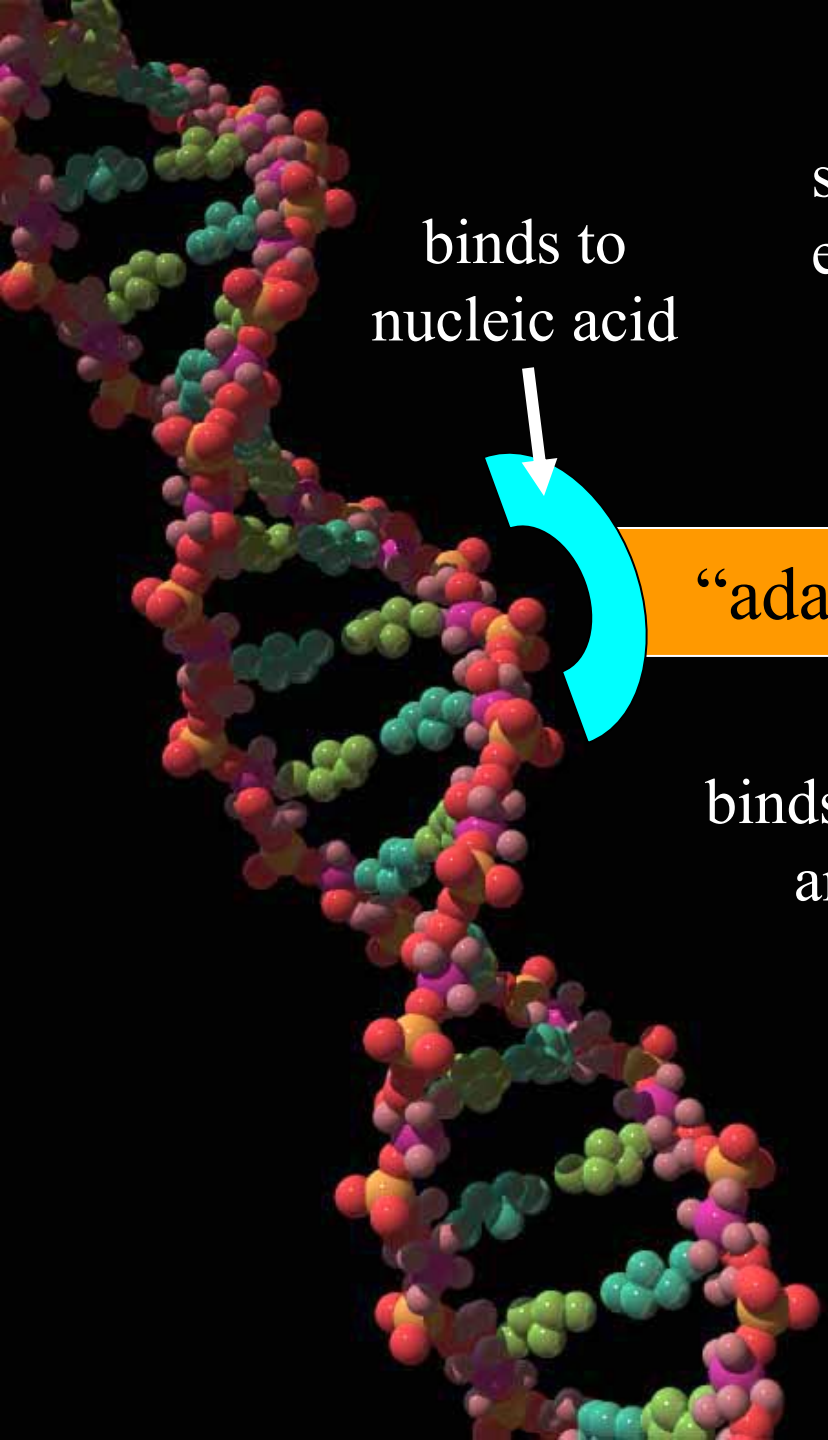
(B) Yet amino acids have specific geometries, which require a system to recognize them.

Crick boldly triangulates:

"...each amino acid would combine chemically, at a special enzyme, with a small molecule which, having a specific hydrogen-bonding surface, would combine specifically with the nucleic acid template.... In its simplest form there would be 20 different kinds of adaptor molecule...."

Crick boldly triangulates:

"...one for each amino acid, and 20 different enzymes to join the amino acid to their adaptors. Sydney Brenner, with whom I have discussed this idea, calls this 'the adaptor hypothesis' since each amino acid is fitted with an adaptor to go on to the template."

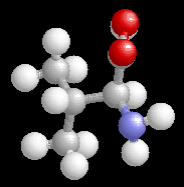


binds to nucleic acid

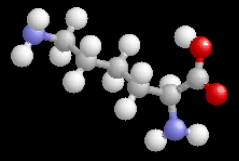
works with a special dedicated enzyme (protein)

"adaptor"

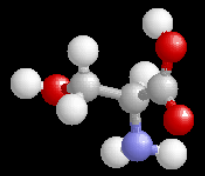
binds to a *specific* amino acid



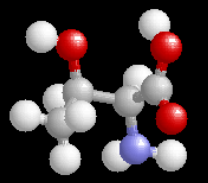
Valine



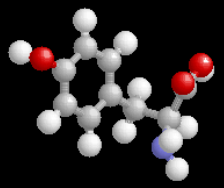
Lysine



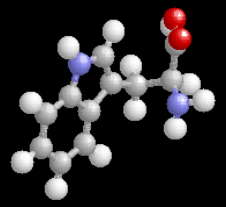
Serine



Threonine

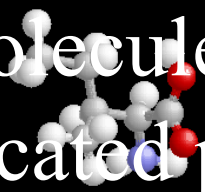


Tyrosine



Tryptophan

Phenylalanine



Isoleucine

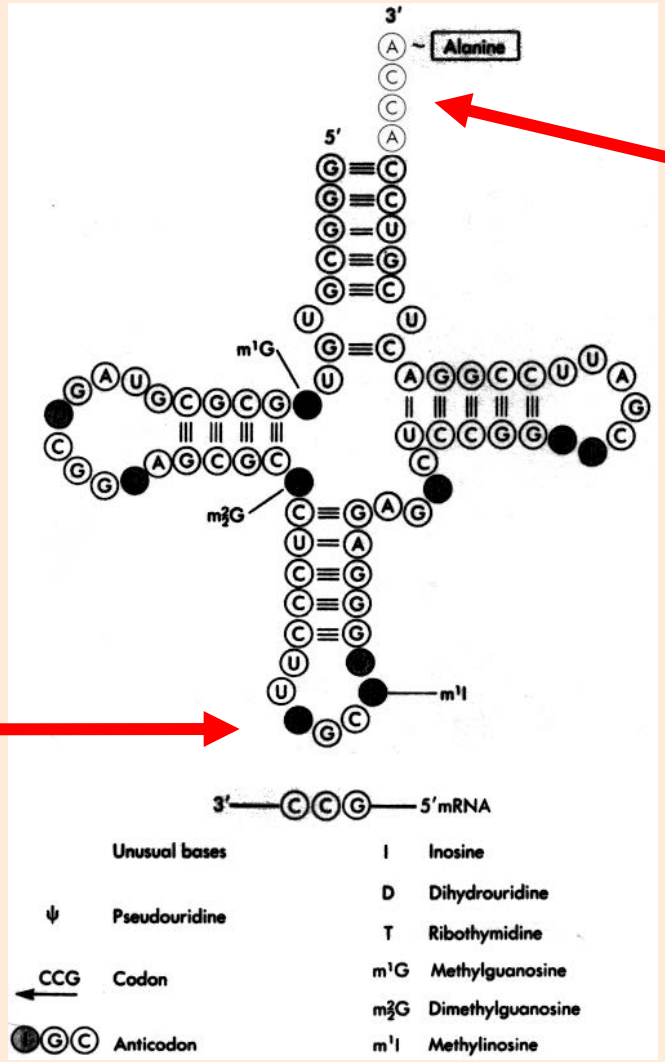
And, by the way – we need 20 of these molecules, with 20 specially dedicated proteins, one for each amino acid.

Crick: there is no evidence yet, but some such mediating molecules ***must*** exist.

"The usual argument presented against this latter scheme is that no such small molecules have been found, but this objection cannot stand."

The inference from *systems-level functional necessity* is very strong.

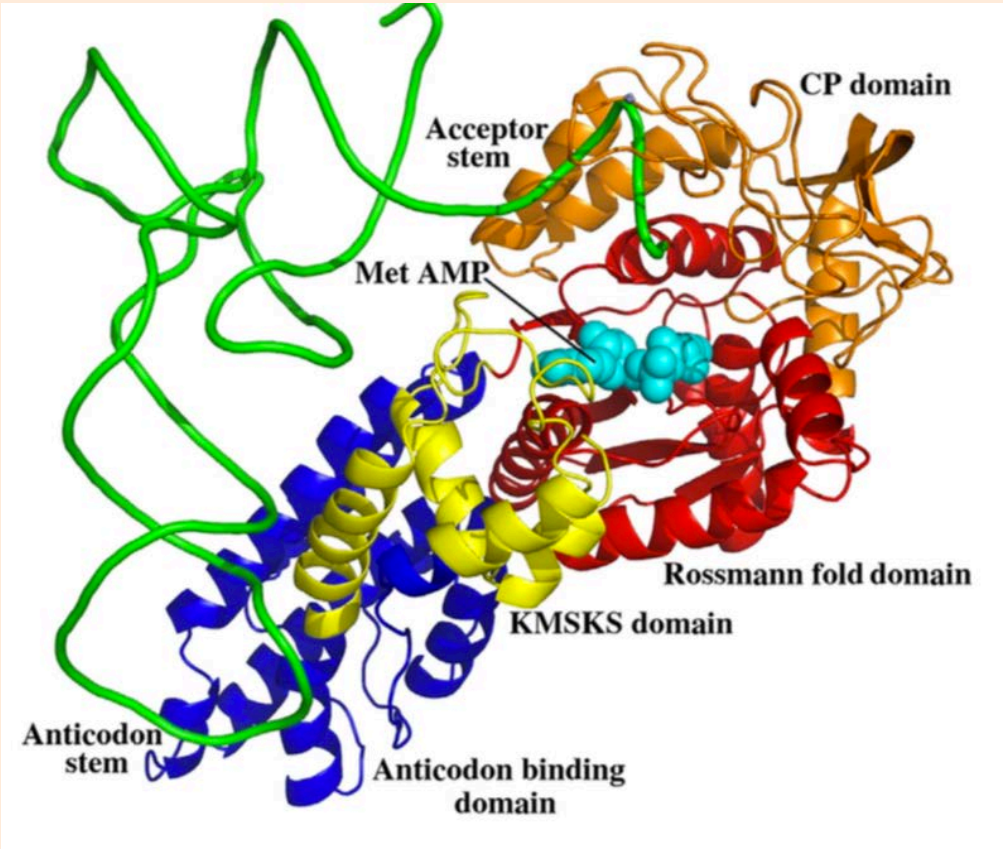
What came to be known as **transfer RNA** – Crick's "adaptor" – was discovered 3 years after Crick's 1955 prediction of its existence. When characterized, it possessed the features Crick said the molecule would need (e.g., a hydrogen-bonding surface [the anticodon]).



CCA stem (the amino acid attachment site)

anticodon

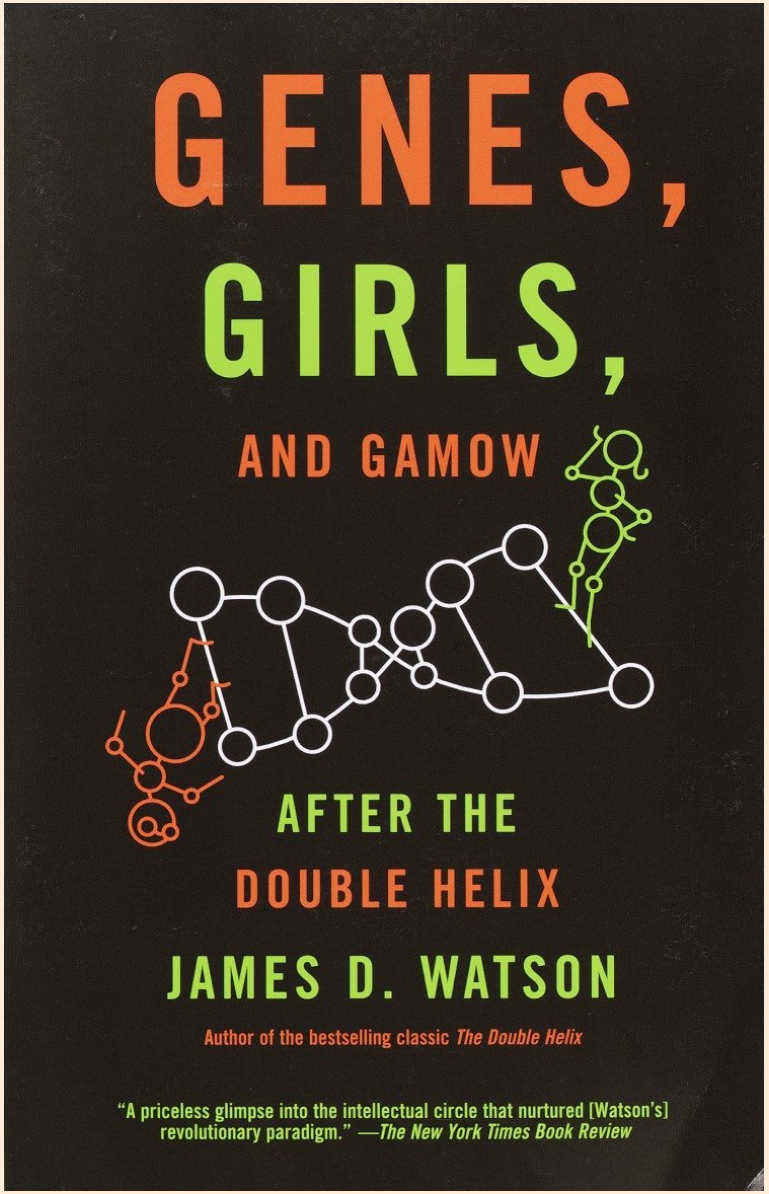
Crick also predicted 20 dedicated enzymes, to attach specific amino acids to their ”adaptors” – again, without having any direct evidence that such enzymes existed: **aminoacyl-tRNA synthetases.**



Docked structure of *E. coli* MetRS–tRNAfMet complex along with Met-AMP.
(figure from Rajendren *et al*. 2018, 402)

Now – on to the brutally honest antagonist of the story.

IV.
Why functional triangulation is really design triangulation: the causal primacy of the organism



In his 2002 autobiography, Watson describes the period in the mid-1950s, when he, Crick, and others in the "RNA Tie Club" were working out the functional implications of DNA for biological information transfer.

The pre-eminent puzzle was the nature of the genetic code.

But the code needed "hardware" – namely, molecular actors (whether proteins or nucleic acids or both) to carry out the role of actually *transferring* information from DNA to amino acids in protein assembly.

F.H.C. Crick

As a founding member of the RNA Tie Club, and one of Crick's closest collaborators, Watson was a recipient of this unpublished manuscript.

ON DEGENERATE TEMPLATES AND THE ADAPTOR HYPOTHESIS

F.H.C. Crick,

Medical Research Council Unit for the Study of the Molecular Structure of Biological Systems,

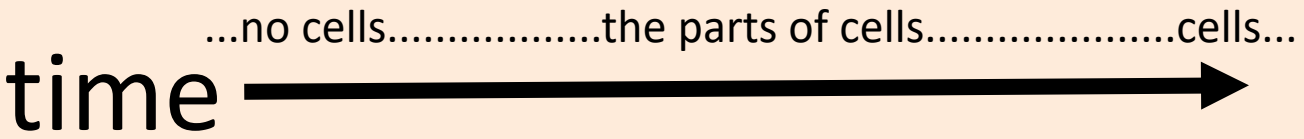
Cavendish Laboratory, Cambridge, England.

But Watson didn't buy the adaptor hypothesis. Why not?

Watson (2002, 139) explains why he didn't like the adaptor hypothesis:

"I did not like the idea at all... More to the point, the adaptor mechanism seemed to me too complicated to have ever evolved at the origin of life."

Watson's biological intuition was bound to an implicit time axis.

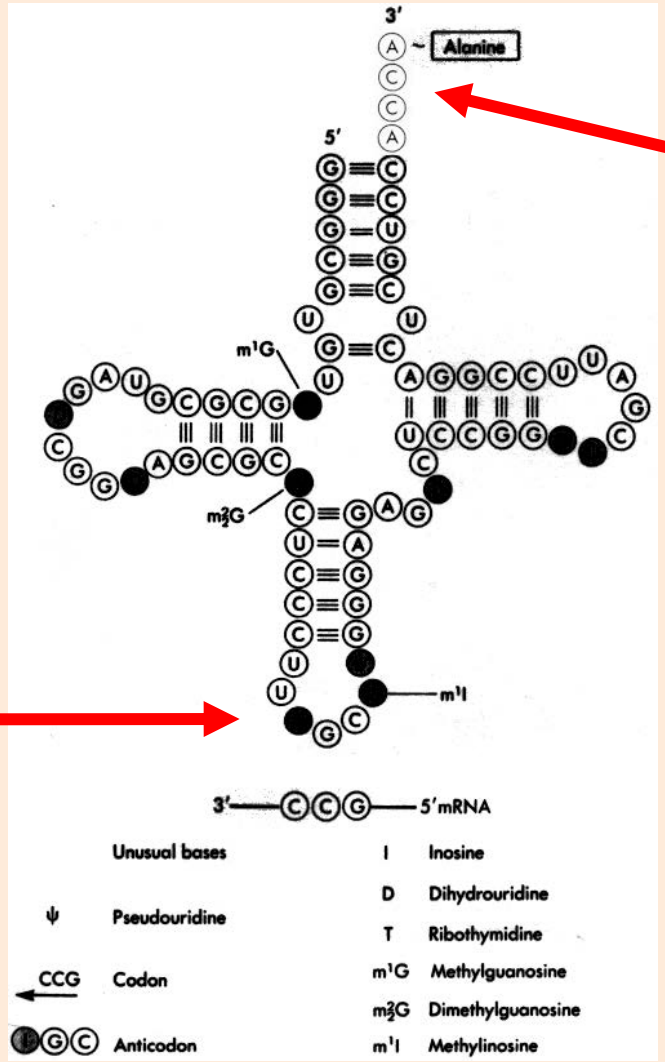


Within the naturalistic picture of life,
complex biological systems cannot arise all at once.
Organisms are fundamentally historical entities,
and “history is just one damn thing after another.”

The same is true, of course, for any naturalistic theory of abiogenesis (origin of life).

Biological complexity can only accrete over time.

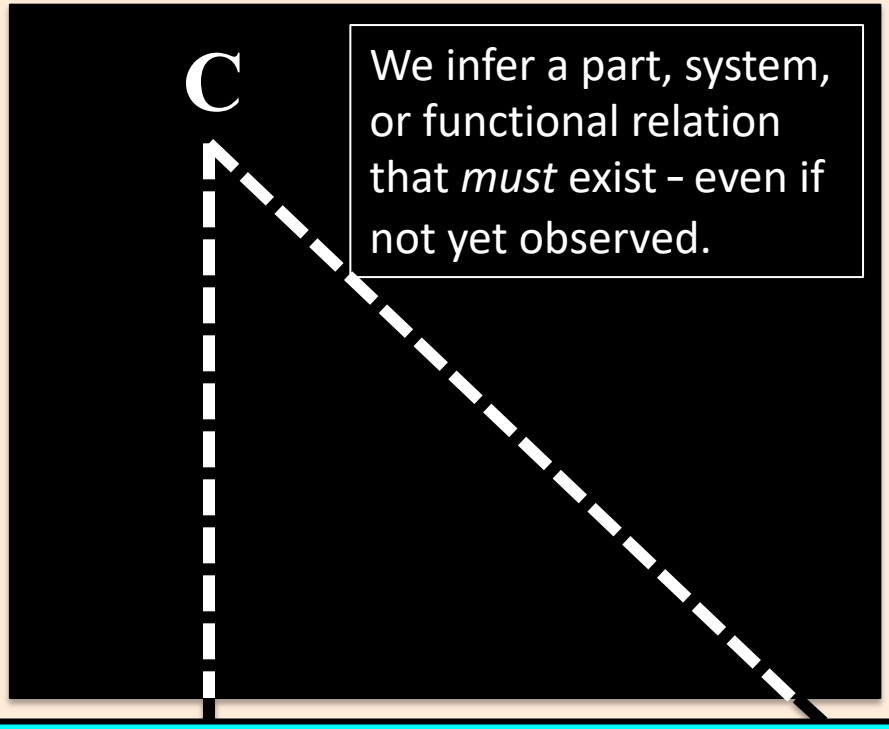
But transfer RNA, or something very much like it, ***had to be there*** – once the facts about DNA, amino acids, and protein assembly were in place.



CCA stem (the amino acid attachment site)

anticodon

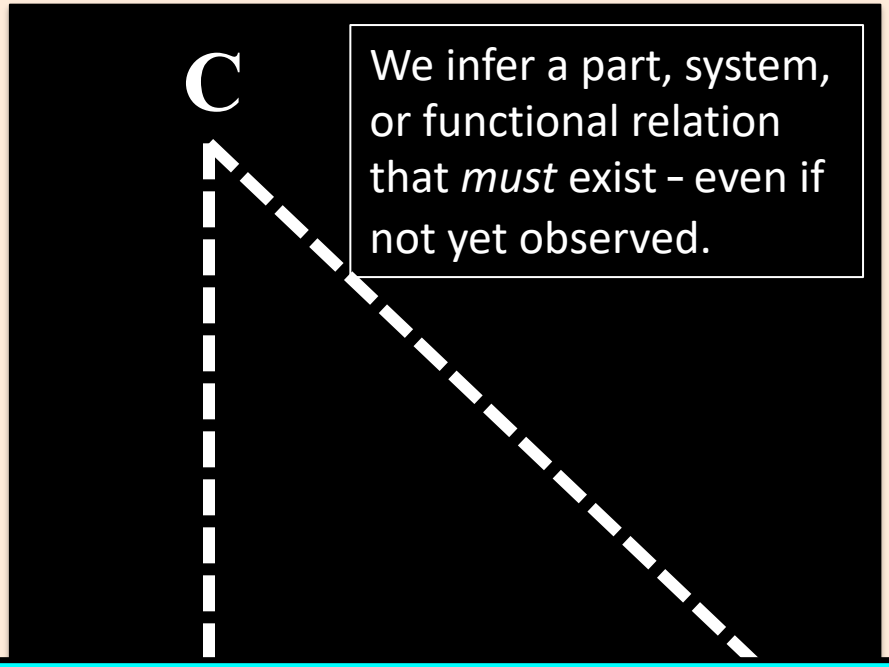
But the time axis, and the complexity-can-only-accrete assumption, aren't there *in the biology itself*.



Organisms and their features as *black boxes*

"Simplest at the start and only then more complicated," and "one must begin with the parts," flow from a *naturalistic metaphysics of explanation*. From philosophy. **Not from organisms themselves. Not from the evidence.**

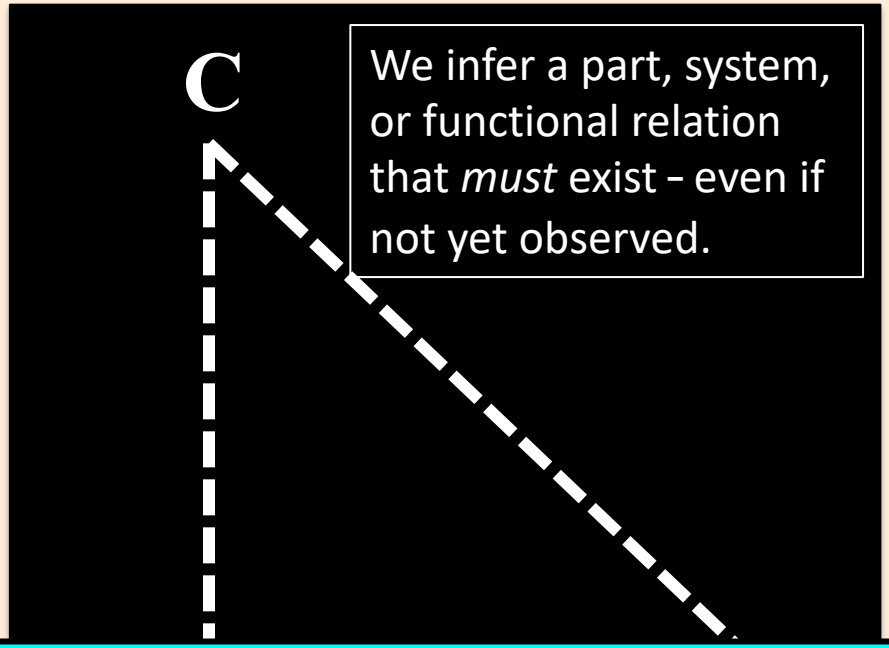
But the time axis, and the complexity-can-only-accrete assumption, aren't there *in the biology itself*.



Organisms and their features as *black boxes*

For biological inquiry – for actually finding things out – triangulation is demonstrably successful. However, the method does make a demand on the investigator.

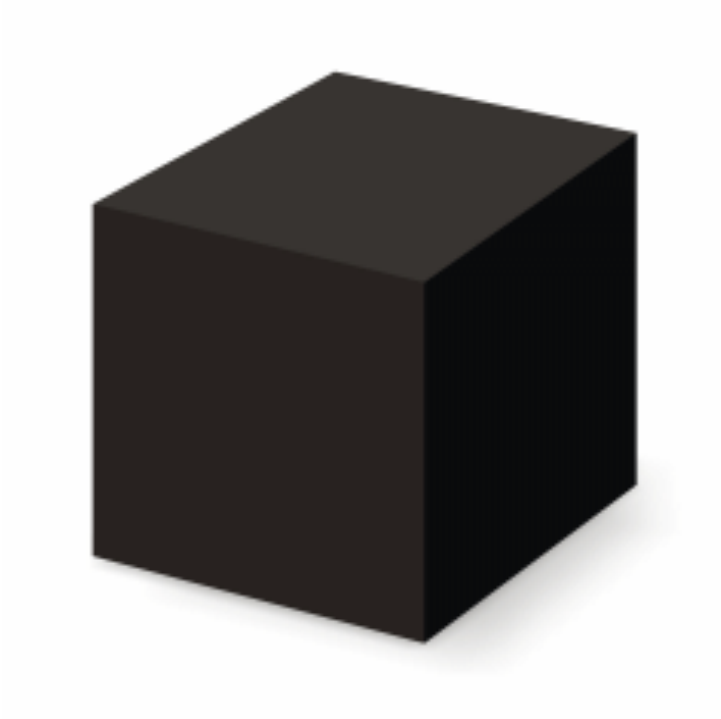
But the time axis, and the complexity-can-only-accrete assumption, aren't there *in the biology itself*.



Organisms and their features as *black boxes*

One must presuppose the prior existence of the ***system as a whole***, to obtain the functional necessity relations ***that warrant any triangulation to its unobserved parts***.

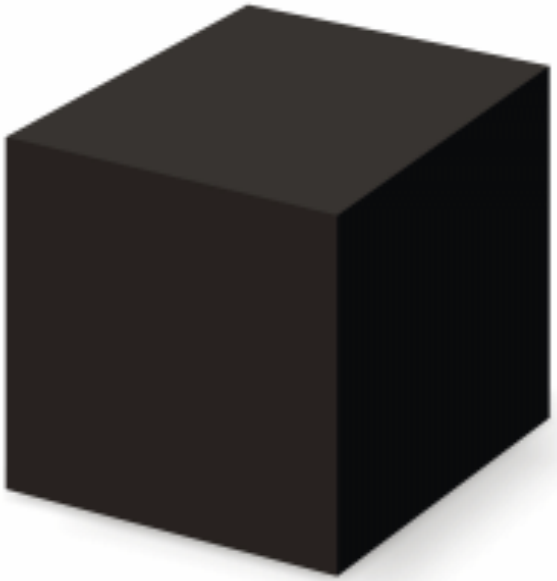
One last thought experiment
will help to illuminate
this point.



Here is a black box that a friend gave you.

Even-numbered days

8:00 AM



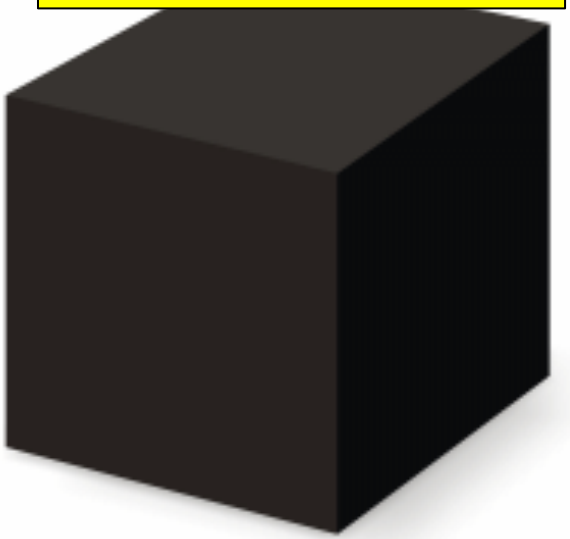
Odd-numbered days

Suppose you observe the following...

On even-numbered days, at 8:00 AM, the black box plays the music of J. S. Bach. On odd-numbered days, the same box plays Beatles music. The box infallibly keeps track of even versus odd (according to the calendar), and always plays Bach, or the Beatles, depending on the value of the date.

Even-numbered days

What can we then infer must exist?



Odd-numbered days

1. **An accurate clock and perpetual calendar.**
2. **Something storing the music of J.S. Bach and the Beatles.**
3. **Something scheduling the "right" music per the day & time.**
4. **A power supply, amplifier, speaker, *et cetera*.**

But pay close attention to the logical structure of the causal inference here.

What is inferentially *basic?*

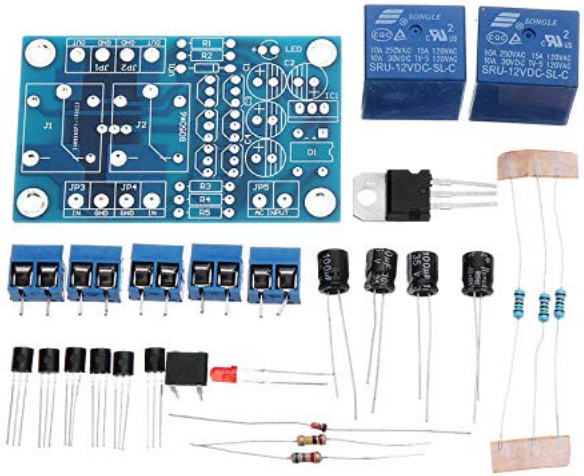
Hint: it is not the *parts* of the black box.

If we do not know the target state and its functions already, we cannot select – from the universe of all possible parts – the correct set.

This logical asymmetry decisively favors the higher level in any functional or causal analysis. **Multiple realizability** and **many-to-one relations** render it intractable to start at the lower level and infer the functions of the whole. ***The space of possibilities is too large.***

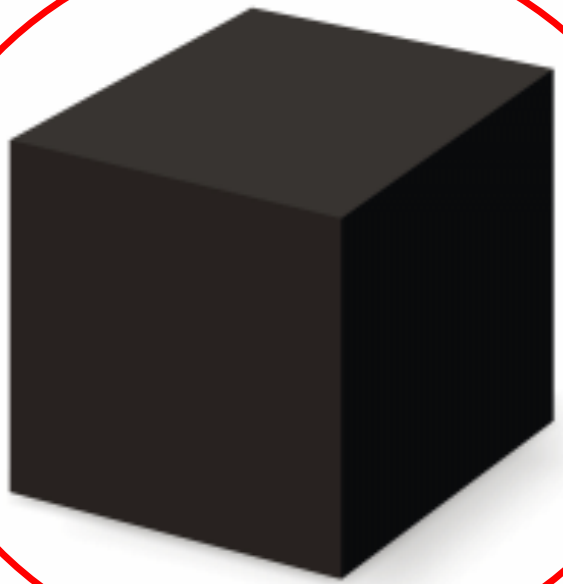
What higher-level system, with its unique functions, is entailed by these parts?

How would you know? The parts represented here (a set already drawn for the sake of illustration from the infinitude of possible entities) are consistent with an indefinitely large number of ***different*** higher-level systems.



The whole – i.e., the ***highest-level system*** – underwrites causal inferences ***to the existence and functions of its parts.***

But we cannot go in the other direction: without the functional whole to guide us, we cannot pick out (from all possibilities) the right parts or relations.



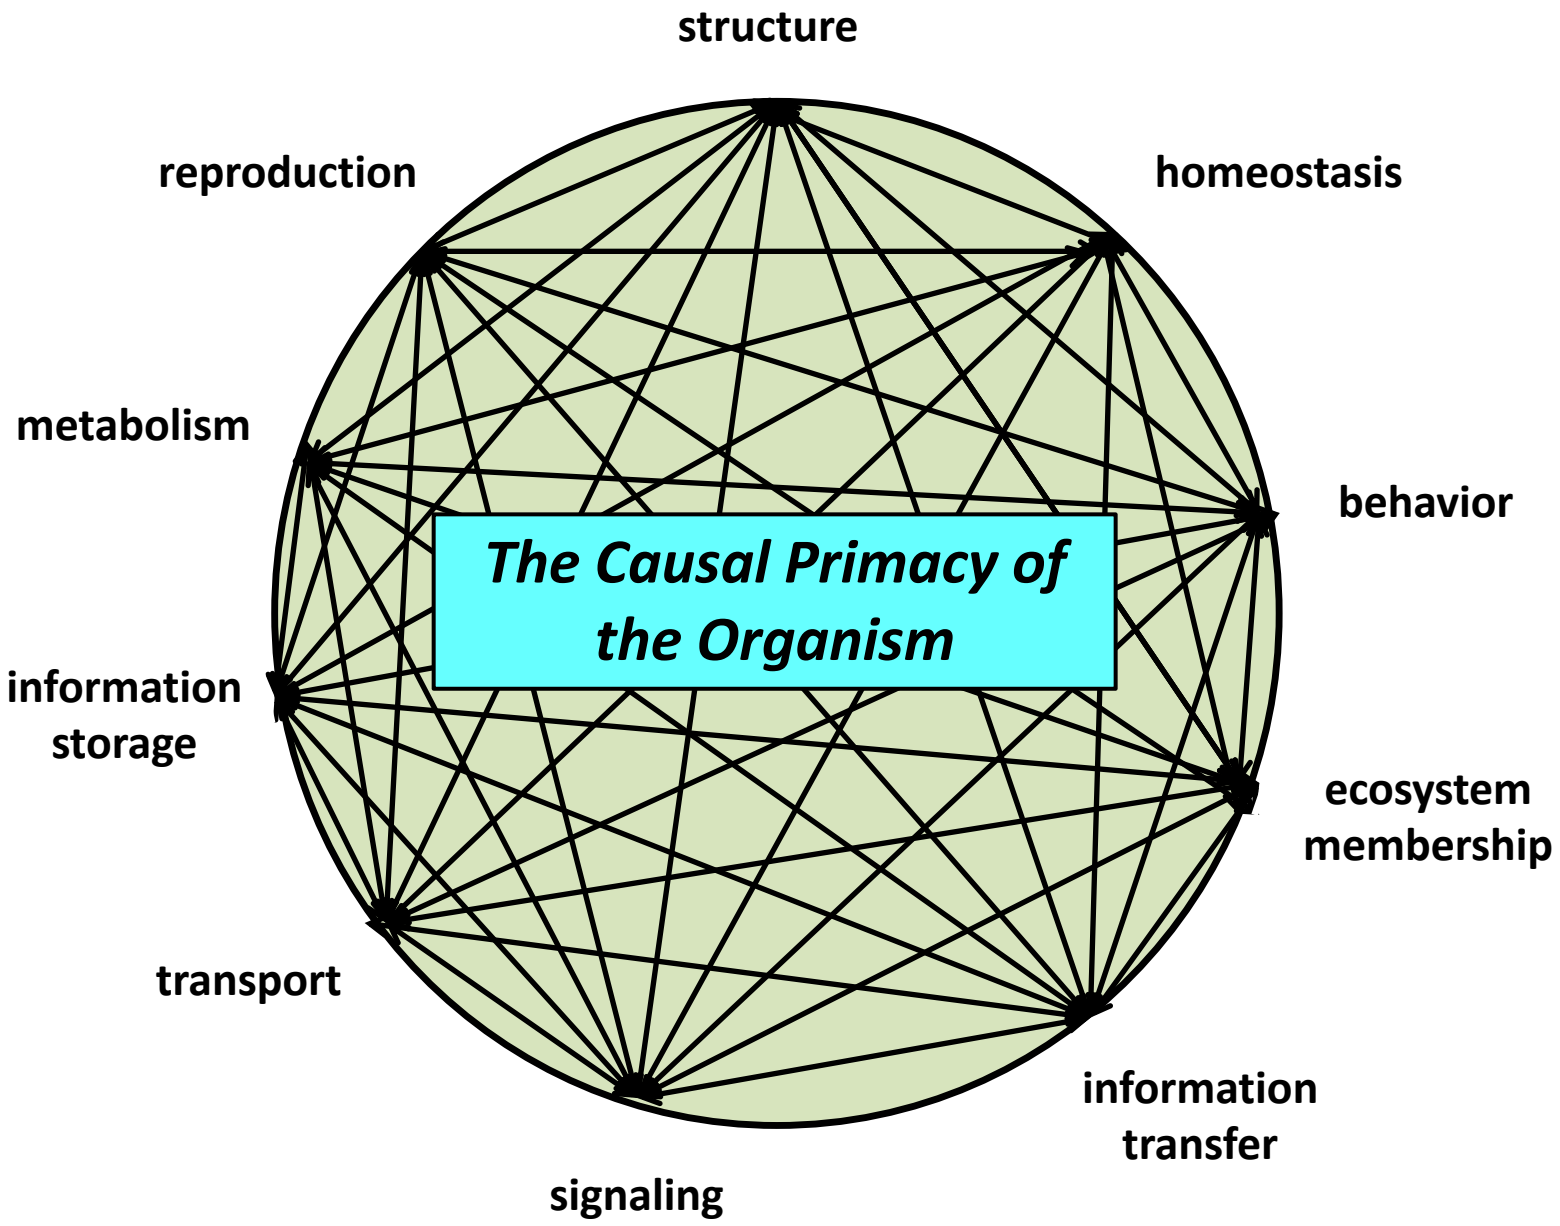
1. **An accurate clock and perpetual calendar.**
2. **Something storing the music of J.S. Bach and the Beatles.**
3. **Something playing the "right" music per the day & time.**
4. **A power supply, amplifier, speaker, *et cetera*.**

Here's that key point again:

The whole – i.e., the ***highest-level system*** – enables or underwrites causal inferences ***to the existence and functions of its parts.***

But we cannot go in the other direction**:** the parts must be selected from the universe of all possibilities – which cannot be accomplished without the prior existence of the functional whole as the target state.

Since we are talking about organisms, and not strange boxes which play Bach and the Beatles, let's call this thesis ***the causal primacy of the organism.***



structure
reproduction
homeostasis
metabolism
behavior
The Causal Primacy of the Organism
information storage
ecosystem membership
transport
information transfer
signaling

Multiple lines of evidence,
accumulated over the past 40 years,
point strongly to the causal
irreducibility of the cell,
and thus its analytical primacy.

Abstract: The central biological question of the 21st century is: how does a viable cell emerge from the bewildering combinatorial complexity of its molecular components? Here, we estimate the combinatorics of self-assembling the protein constituents of a yeast cell, a number so vast that the functional interactome could only have emerged by iterative hierarchic assembly of its component sub-assemblies. A protein can undergo both reversible denaturation and hierarchic self-assembly spontaneously, but a functioning interactome must expend energy to achieve viability. Consequently, it is implausible that a completely "denatured" cell could be reversibly renatured spontaneously, like a protein. Instead, new cells are generated by the division of pre-existing cells, an unbroken chain of renewal tracking back through contingent conditions and evolving responses to the origin of life on the prebiotic earth. We surmise that this non-deterministic temporal continuum could not be reconstructed *de novo* under present conditions.

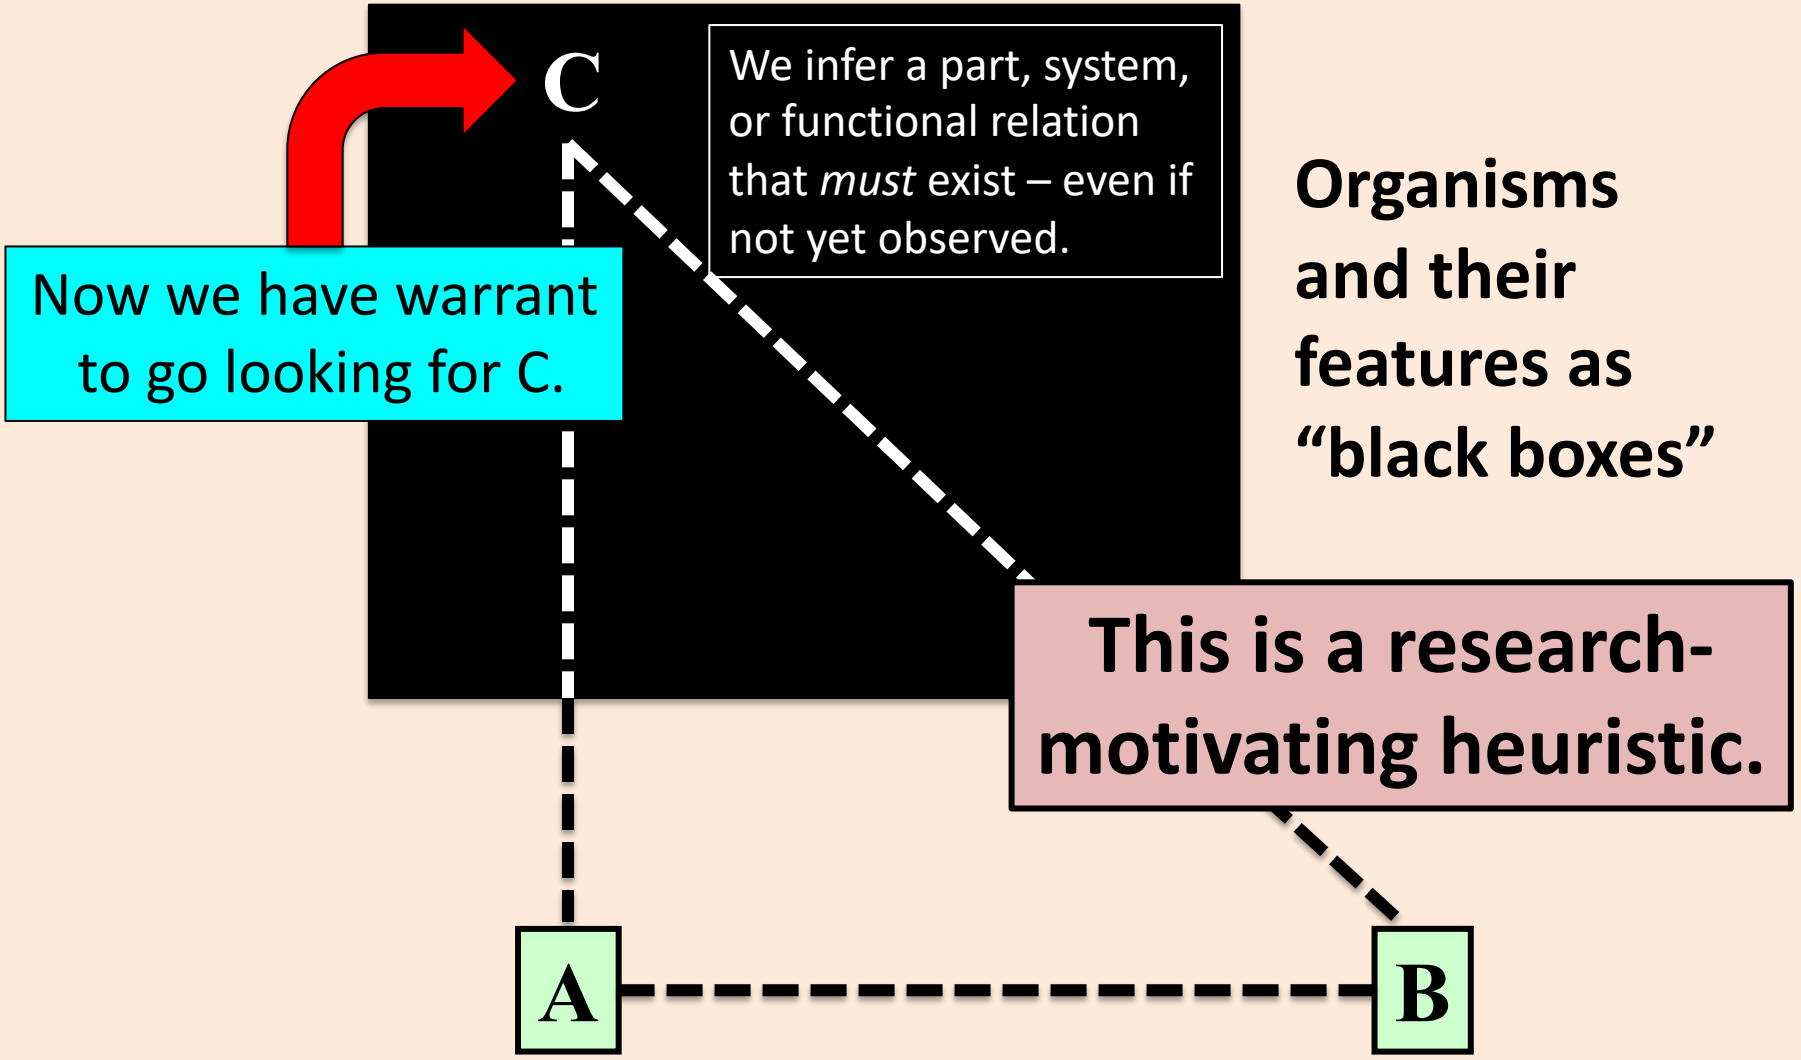
Bill Dembski stopped his calculations here,
at 100 proteins, even though real cells have at least
300 proteins. There was no point in going any further.

What metaphysics of explanation enables one to start with the whole organism?



Design.
